

**Supplementary Table S1. Implications of trace metal elements in diabetic therapy.**

Metal	Method	Samples	Results	References
<b>Copper</b>	Oral tetrathiomolybdate intake (TETA, copper chelating agent)	C57BL/KsJ-db/db mice	TETA improves insulin resistance and restored glucose intolerance, reduces serum triglyceride levels.	[80]
	Oral TETA intake	Wistar rats, injection of STZ,	TETA reduces diabetic complications damage, increases the activity of SOD.	[158]
	Oral TETA intake	Wistar rats, injection of STZ,	TETA attenuates diabetic kidney disease by suppressing the activity of activation of TGF- $\beta$ signaling.	[159]
	Pretreat with CuCl <sub>2</sub> ·2H <sub>2</sub> O	3T3-L1 cells	High copper level can restore the activity of insulin signaling by down-regulating PTEN protein in adipocytes.	[86]
	Copper-containing fabric bedding	High fat, high cholesterol diet induced obesity mice	With contrary of control, mouse housed on copper-containing fabric bedding has less Reduces body weight, increases glucose tolerance.	[160]
	Foods with high level zinc	U.S. T2D Women	In part, higher zinc intake can diminish the risk of T2D.	[161]
	Foods contain zinc	French Women, a prospective cohort study	Obesity women with zinc intake >8mg/day and low Cu/Zn ratio reduces the risk of T2D.	[162]

<b>Zinc</b>	Oral zinc sulfate intake	T2D patients, adult-onset	Zinc supplementation improves glucose control, changes serum cholesterol level and the ratio of cholesterol/high-density lipoprotein. Zinc sulfate and multivitamin/mineral has the potential to protect diabetes.	[163]
	Oral intake of zinc threoninate chelate	Wistar rats, STZ injection	Zinc threoninate chelate reduces serum glucose concentration, increases insulin levels and the activation of Cu/Zn-SOD.	[164]
	Oral zinc sulfate intake	Swiss albino rats, STZ injection	Zinc sulfate increases GSH levels in kidney, enhances antioxidant potential, defenses kidney damage.	[165]
<b>Iron</b>	Oral DFO intake	White diabetic patients with high levels of ferritin	To high-ferritin diabetic patients, DFO has a positive effect to reduce glucose, triglyceride and HbA1c.	[166]
	Dietary iron-restriction (35 mg/kg iron);	Ob/Ob mice with T2D	Iron-restricted diet can ameliorate insulin sensitivity and $\beta$ -islet cell function.	[167]
	Oral DFO intake	KKAy mice	Iron chelator decreases macrophage infiltration into fat, leading to lower inflammatory cytokines and oxidative stress, which ameliorates a vicious cycle in obesity.	[168]
	Oral ferrous fumarate intake	Non-anemic pregnant women	Early iron supplementation increases the risk of gestational diabetes.	[169]
<b>Manganese</b>	Injection of 12 mg/kg MnCl <sub>2</sub>	C57BL/6J mice with a high-fat diet	Mn treatment increases insulin secretory capacity of $\beta$ -islet cell and the activity of Mn-SOD.	[102]
	Gavage MnCl <sub>2</sub> solution or cells pretreated with MnCl <sub>2</sub>	Zucker diabetic fatty rats	Mn supplementation increases adiponectin and protect endothelial dysfunction in diabetes.	[103]

Gavage MnCl <sub>2</sub> solution or cells pretreated with MnCl <sub>2</sub>	Zucker diabetic fatty rats	Mn supplements can decrease ICAM-1 expression and ROS, reduces adhesion of monocytes to endothelial cells, diminishes the risk of vascular disease in diabetic animals	[170]
Consume food with Mn	Chinese adults with T2D	Mn intake and the incidence of diabetes have a negative association.	[171]

T2D: Diabetes mellitus type 2; TETA, triethylenetetramine; STZ, streptozotocin; SOD, superoxide dismutase; GSH, glutathione; DFO, deferoxamine.
