[†] Dedicated to Robert Finn on the occasion of his 100th birthday.

Abstract: We quantized the interaction of gravity with Yang–Mills and spinor fields; hence, offering a quantum theory incorporating all four fundamental forces of nature. Let us abbreviate the spatial Hamilton functions of the standard model by H_{SM} and the Hamilton function of gravity by H_G . Working in a fiber bundle E with base space $S_0 = \mathbb{R}^n$, where the fiber elements are Riemannian metrics, we can express the Hamilton functions in the form $H_G + H_{SM} = H_G + t^{-\frac{2}{3}} \tilde{H}_{SM}$, if $n = 3$, where \tilde{H}_{SM} depends on metrics σ_{ij} satisfying $\det \sigma_{ij} = 1$. In the quantization process, we quantize H_G for general σ_{ij} but \tilde{H}_{SM} only for $\sigma_{ij} = \delta_{ij}$ by the usual methods of QFT. Let v resp. ψ be the spatial eigendistributions of the respective Hamilton operators, then, the solutions u of the Wheeler–DeWitt equation are given by $u = wv\psi$, where w satisfies an ODE and u is evaluated at (t, δ_{ij}) in the fibers.

Keywords: quantization of gravity; quantum gravity; standard model; temporal and spatial eigenfunctions; Fourier quantization; symmetric spaces

1. Introduction

General relativity is a Lagrangian theory, i.e., the Einstein equations are derived as the Euler–Lagrange equation of the Einstein–Hilbert functional

$$\int_N (\bar{R} - 2\Lambda), \quad (1)$$

where $N = N^{n+1}$, $n \geq 3$, is a globally hyperbolic Lorentzian manifold, \bar{R} is the scalar curvature, and Λ is a cosmological constant. We also omitted the integration density in the integral. In order to apply a Hamiltonian description of general relativity, one usually defines a time function x^0 and considers the foliation of N given by the slices

$$M(t) = \{x^0 = t\}. \quad (2)$$

We may, without loss of generality, assume that the spacetime metric splits

$$ds^2 = -w^2(dx^0)^2 + g_{ij}(x^0, x)dx^i dx^j, \quad (3)$$

cf. [1] (Theorem 3.2). Then, the Einstein equations also split into a tangential part

$$G_{ij} + \Lambda g_{ij} = 0 \quad (4)$$

and a normal part

$$G_{\alpha\beta} \nu^\alpha \nu^\beta - \Lambda = 0, \quad (5)$$

where the naming refers to the given foliation. For the tangential Einstein equations, one can define equivalent Hamilton equations due to the groundbreaking paper by Arnowitt,

Deser, and Misner [2]. The normal Einstein equations can be expressed by the so-called Hamilton condition

$$\mathcal{H} = 0, \quad (6)$$

where \mathcal{H} is the Hamiltonian used in defining the Hamilton equations. In the canonical quantization of gravity, the Hamiltonian is transformed to a partial differential operator of a hyperbolic type $\hat{\mathcal{H}}$ and the possible quantum solutions of gravity are supposed to satisfy the so-called Wheeler–DeWitt equation

$$\hat{\mathcal{H}}u = 0 \quad (7)$$

in an appropriate setting, i.e., only the Hamilton condition, (6) was quantized, or equivalently, the normal Einstein equation, while the tangential Einstein equations were ignored.

In [1], we solved the Equation (7) in a fiber bundle E with the base space \mathcal{S}_0 ,

$$\mathcal{S}_0 = \{x^0 = 0\} \equiv M(0), \quad (8)$$

and fibers $F(x)$, $x \in \mathcal{S}_0$,

$$F(x) \subset T_x^{0,2}(\mathcal{S}_0), \quad (9)$$

the elements of which are the positive definite symmetric tensors of order two, the Riemannian metrics in \mathcal{S}_0 . The hyperbolic operator $\hat{\mathcal{H}}$ is then expressed in the form

$$\hat{\mathcal{H}} = -\Delta - (R - 2\Lambda)\varphi, \quad (10)$$

where Δ is the Laplacian of the DeWitt metric given in the fibers, R the scalar curvature of the metrics $g_{ij}(x) \in F(x)$, and φ is defined by

$$\varphi^2 = \frac{\det g_{ij}}{\det \rho_{ij}}, \quad (11)$$

where ρ_{ij} is a fixed metric in \mathcal{S}_0 , such that, instead of densities, we consider functions. The Wheeler–DeWitt equation could be solved in E but only as an abstract hyperbolic equation. The solutions could not be split into corresponding spatial and temporal eigenfunctions.

In a recent paper [3], we overcame this difficulty by quantizing the Hamilton equations instead of the Hamilton condition.

As a result, we obtained the equation

$$-\Delta u = 0 \quad (12)$$

in E , where the Laplacian is the Laplacian in (10). The lower order terms of $\hat{\mathcal{H}}$

$$(R - 2\Lambda)\varphi \quad (13)$$

were eliminated during the quantization process. This result was valid for all dimensions $3 \leq n$, provided $n \neq 4$.

The fibers add additional dimensions to the quantized problem, namely,

$$\dim F = \frac{n(n+1)}{2} \equiv m+1. \quad (14)$$

The fiber metric, the DeWitt metric, which is responsible for the Laplacian in (12), can be expressed in the form

$$ds^2 = -\frac{16(n-1)}{n}dt^2 + \varphi G_{AB}d\tilde{\zeta}^A d\tilde{\zeta}^B, \quad (15)$$

where the coordinate system is

$$(\tilde{\zeta}^a) = (\tilde{\zeta}^0, \tilde{\zeta}^A) \equiv (t, \zeta^A). \quad (16)$$

The $(\tilde{\zeta}^A)$, $1 \leq A \leq m$, are coordinates for the hypersurface

$$M \equiv M(x) = \{(g_{ij}) : t^4 = \det g_{ij}(x) = 1, \forall x \in \mathcal{S}_0\}. \quad (17)$$

We also assumed that $\mathcal{S}_0 = \mathbb{R}^n$ and that the metric ρ_{ij} in (11) is the Euclidean metric δ_{ij} . It is well-known that M is a symmetric space

$$M = SL(n, \mathbb{R})/SO(n) \equiv G/K. \quad (18)$$

It is also easily verified that the induced metric of M in E is isometric to the Riemannian metric of the coset space G/K .

Now, we were in a position to use the separation of variables, namely, we wrote a solution of (12) in the form

$$u = w(t)v(\tilde{\zeta}^A), \quad (19)$$

where v is a spatial eigenfunction of the induced Laplacian of M

$$-\Delta_M v \equiv -\Delta v = (|\lambda|^2 + |\rho|^2)v \quad (20)$$

and w is a temporal eigenfunction satisfying the ODE

$$\ddot{w} + mt^{-1}\dot{w} + \mu_0 t^{-2}w = 0 \quad (21)$$

with

$$\mu_0 = \frac{16(n-1)}{n}(|\lambda|^2 + |\rho|^2). \quad (22)$$

The eigenfunctions of the Laplacian in G/K are well-known and we chose the kernel of the Fourier transform in G/K in order to define the eigenfunctions. This choice also allowed us to use the Fourier quantization similar to the Euclidean case, such that the eigenfunctions were transformed to Dirac measures and the Laplacian to a multiplication operator in the Fourier space.

In the present paper, we quantize the Einstein–Hilbert functional combined with the functionals of the other fundamental forces of nature, i.e., we look at the Lagrangian functional

$$\begin{aligned} J = & \alpha_N^{-1} \int_{\tilde{\Omega}} (\tilde{R} - 2\Lambda) - \int_{\tilde{\Omega}} \frac{1}{4} \gamma_{\bar{a}\bar{b}} \tilde{\delta}^{\mu\rho_2} \tilde{\delta}^{\lambda\rho_1} F_{\mu\rho_1}^{\bar{a}} F_{\rho_2\lambda}^{\bar{b}} \\ & - \int_{\tilde{\Omega}} \left\{ \frac{1}{2} \tilde{\delta}^{\mu\lambda} \gamma_{\bar{a}\bar{b}} \Phi_{\mu}^{\bar{a}} \Phi_{\lambda}^{\bar{b}} + V(\Phi) \right\} \\ & + \int_{\tilde{\Omega}} \left\{ \frac{1}{2} [\tilde{\psi}_I E_a^{\mu} \gamma^a (D_{\mu} \psi)^I + \overline{\tilde{\psi}_I E_a^{\mu} \gamma^a (D_{\mu} \psi)^I}] + m \tilde{\psi}_I \psi^I \right\}, \end{aligned} \quad (23)$$

where α_N is a positive coupling constant, $\tilde{\Omega} \in N = N^{n+1}$ and N is a globally hyperbolic spacetime with metric $\tilde{g}_{\alpha\beta}$, $0 \leq \alpha, \beta \leq n$, where the metric splits as in (3).

The functional J consists of the Einstein–Hilbert functional, the Yang–Mills and Higgs functional, and a massive Dirac term.

The Yang–Mills field (A_{μ})

$$A_{\mu} = f_{\bar{c}} A_{\mu}^{\bar{c}} \quad (24)$$

corresponds to the adjoint representation of a compact, semi-simple Lie group \mathcal{G} with Lie algebra \mathfrak{g} . The $f_{\bar{c}}$,

$$f_{\bar{c}} = (f_{\bar{c}\bar{b}}^{\bar{a}}) \quad (25)$$

are the structure constants of \mathfrak{g} .

We assume the Higgs field $\Phi = (\Phi^{\bar{a}})$ to have complex valued components.

The spinor field $\psi = (\psi_A^I)$ has a spinor index A , $1 \leq A \leq n_1$, and a color index I , $1 \leq I \leq n_2$. Here, we suppose that the Lie group has a unitary representation R , such that

$$t_{\bar{c}} = R(f_{\bar{c}}) \quad (26)$$

are anti-Hermitian matrices acting on \mathbb{C}^{n_2} . The symbol $A_\mu \psi$ is now defined by

$$A_\mu \psi = t_{\bar{c}} \psi A_\mu^{\bar{c}}. \quad (27)$$

There are some major difficulties in achieving a quantization of the functional in (23). Quantizing the Hamilton equations, to avoid the problem with the scalar curvature term, runs into technical difficulties, even if the required quantization of the matter fields in the curved spacetimes could be achieved since the resulting operator would no longer be hyperbolic because the elliptic parts of the gravitational resp. matter Hamiltonians would have different signs in the case of $n = 3$. This particular problem would not occur when the Hamilton condition would be quantized. The Hamilton condition has the form

$$H_G + H_{YM} + H_D + H_H = 0, \quad (28)$$

where the subscripts refer to gravity, Yang–Mills, Dirac, and Higgs. On the left-hand side are the Hamilton functions of the respective fields. They depend on the Riemannian metrics g_{ij} , the Yang–Mills connections, and the spinor and Higgs fields. The main part of the quantized gravitational Hamiltonian is a second-order hyperbolic differential operator with respect to the variables g_{ij} while the scalar curvature term R is of zero-order. With this in mind, we also shall apply these categories to the gravitational Hamilton function where the main part, quadratic in the conjugate momenta, is said to be of the second-order and the zero-order terms consist of the scalar curvature and the cosmological constant Λ . Similarly, we consider the matter Hamilton functions to be zero-order terms with respect to the metric g_{ij} , i.e., there is no qualitative difference by assuming g_{ij} to be flat or non-flat, or more precisely, quantizing a matter Hamiltonian in a curved spacetime (when g_{ij} is a given, fixed metric and not a variable) is qualitatively the same as quantizing it for the Euclidean metric, though the task is certainly more difficult.

Thus, the difficulties arising from quantizing the Hamilton condition can best be explained by considering the Wheeler–DeWitt equation

$$\hat{H}_G u = 0 \quad \text{in } E, \quad (29)$$

cf. (7), where we wrote $\hat{\mathcal{H}}$ instead of \hat{H}_G . This is a hyperbolic differential equation, which can be expressed by

$$\hat{H}_G u = -\Delta u + \varphi(R - 2\Lambda)u = 0, \quad (30)$$

where the Laplacian is the Laplacian of the fiber metric (15). In the coordinate system (16), we have

$$\hat{H}_G u = t^{-m} \frac{\partial}{\partial t} \left(t^m \frac{\partial u}{\partial t} \right) - t^{-2} \Delta_M u + t^2 (R - 2\Lambda)u, \quad (31)$$

where M is the hypersurface (17). Since M is isometric to the symmetric space (18) it is mathematically irresistible to solve (31) by applying separation of variables and using the functions of the Fourier kernel of M as spatial eigenfunctions v , where $v = v(\sigma_{ij})$, σ_{ij} are the elements of M . Since

$$g_{ij}(x) = t^{\frac{4}{n}} \sigma_{ij}(x) \quad (32)$$

the critical term R can be expressed as

$$R(g_{ij}) = t^{-\frac{4}{n}} R(\sigma_{ij}) \quad (33)$$

due to the relation between the scalar curvatures of conformal metrics.

Thus, it is obvious that the ansatz

$$u = wv, \quad (34)$$

where $w = w(t)$ solves an ODE is only possible if $R(\sigma_{ij})$ is constant

$$R(\sigma_{ij}) = \lambda_0. \quad (35)$$

The constant is arbitrary but determined by the metrics we consider to be important, e.g., in the case of a black hole, we would choose σ_{ij} to be the limit metric of a converging sequence of Cauchy hypersurfaces of the interior region of the black hole, which converge to the event horizon topologically but the induced metrics of which converge to a Riemannian metric, cf. [4,5] or [6] (Chapters 4 and 5). In the present case, where we want to include the matter fields of the standard model, we could choose $\sigma_{ij} = \delta_{ij}$.

However, this ansatz implies that the Wheeler–DeWitt equation is not solved for all (t, σ_{ij}) but only for the σ_{ij} satisfying (35). Given the simplicity and mathematical beauty of the solution, we are inclined to accept this restriction.

Let us now consider the quantization of the Hamilton condition (28) taking all Hamilton functions into account. In view of the relation (32), let us propose the following model: If we were able to express the non-gravitational Hamiltonians as

$$H_{YM} = t^p \tilde{H}_{YM}, \quad H_D = t^p \tilde{H}_D, \quad H_H = t^p \tilde{H}_H, \quad (36)$$

where the embellished Hamiltonians depend on σ_{ij} , then, by choosing in addition $n = 3$ and $\sigma_{ij} = \delta_{ij}$, these Hamiltonians could be quantized by the known methods of QFT, if the Lie groups would be chosen appropriately. The Wheeler–DeWitt equation would then not be solved for all (t, σ_{ij}) but only for (t, δ_{ij}) . However, the spatial eigendistributions of the Hamilton operator \hat{H}_G , i.e., the eigendistributions of the Laplacian of M , cf. (20), would still be used but they would be evaluated at $\sigma_{ij} = \delta_{ij}$.

In Section 4, we prove that the expressions in (36) are indeed valid with $p = -\frac{2}{3}$ provided $n = 3$ and provided that the mass term in the Dirac Lagrangian and the Higgs Lagrangian is slightly modified. The embellished Hamiltonians are then standard Hamiltonians without any modifications, for details, we refer to Section 4. The Hamilton constraint then has the form

$$\begin{aligned} H &= H_G + H_{YM} + H_H + H_D \\ &= H_G + t^{-\frac{2}{3}} (\tilde{H}_{YM} + \tilde{H}_H + \tilde{H}_D) \\ &\equiv H_G + t^{-\frac{2}{3}} \tilde{H}_{SM} = 0, \end{aligned} \quad (37)$$

where the subscript SM refers to the fields of the standard model or a corresponding subset of fields. The solutions of the Wheeler–DeWitt equation

$$\hat{H}u = 0 \quad (38)$$

can then be achieved by using the separation of variables. We proved:

Theorem 1. Let $n = 3$, $v = e_{\lambda, b_0}$ and let ψ be an eigendistribution of \tilde{H}_{SM} when $\sigma_{ij} = \delta_{ij}$ such that

$$-\Delta_M e_{\lambda, b_0} = (|\lambda|^2 + 1)e_{\lambda, b_0}, \quad (39)$$

$$\tilde{H}_{SM}\psi = \lambda_1\psi, \quad \lambda_1 \geq 0, \quad (40)$$

and let w be a solution of the ODE

$$t^{-m} \frac{\partial}{\partial t} (t^m \frac{\partial w}{\partial t}) + \frac{32}{3} (|\lambda|^2 + 1) t^{-2} w + \frac{32}{3} \alpha_N^{-1} \lambda_1 t^{-\frac{2}{3}} w + \frac{64}{3} \alpha_N^{-2} \Lambda t^2 w = 0 \quad (41)$$

then

$$u = w e_{\lambda, b_0} \psi \quad (42)$$

is a solution of the Wheeler–DeWitt equation

$$\hat{H}u = 0, \quad (43)$$

where e_{λ, b_0} is evaluated at $\sigma_{ij} = \delta_{ij}$ and where we note that $m = 5$.

We shall refer to e_{λ, b_0} and ψ as the spatial eigenfunctions and w as the temporal eigenfunction.

Remark 1. We could also apply the respective Fourier transforms to $-\tilde{\Delta} e_{\lambda, b_0}$ resp. $\tilde{H}_{SM} \psi$ and consider

$$w \hat{e}_{\lambda, b_0} \hat{\psi} \quad (44)$$

as the solution in Fourier space, where $\hat{\psi}$ would be expressed with the help of the ladder operators.

The temporal eigenfunctions are analyzed in Section 5. They must satisfy an ODE of the form

$$\ddot{w} + 5t^{-1} \dot{w} + m_1 t^{-2} w + m_2^2 t^{-\frac{2}{3}} w + m_3 t^2 w = 0, \quad (45)$$

where

$$m_1 \geq \frac{32}{3}, \quad m_2 \geq 0, \quad m_3 \in \mathbb{R}. \quad (46)$$

For simplicity, we shall only state the result when $m_3 = 0$, which is tantamount to setting $\Lambda = 0$.

Theorem 2. Assume $m_3 = 0$ and $m_2 > 0$, then the solutions of the ODE (45) are generated by

$$J(\frac{3}{2} \sqrt{m_1 - 4} i, \frac{3}{2} m_2 t^{\frac{2}{3}}) t^{-2} \quad (47)$$

and

$$J(-\frac{3}{2} \sqrt{m_1 - 4} i, \frac{3}{2} m_2 t^{\frac{2}{3}}) t^{-2}, \quad (48)$$

where $J(\lambda, t)$ is the Bessel function of the first kind.

Lemma 1. The solutions in the theorem above diverge to complex infinity if t tends to zero and they converge to zero if t tends to infinity.

2. Definitions and Notations

Greek indices α, β range from 0 to n , Latin i, j, k from 1 to n , and we stipulate $0 \leq a, b \leq n$ but $1 \leq a', b' \leq n$. Barred indices \bar{a} refer to the Lie algebra \mathfrak{g} , $1 \leq \bar{a} \leq n_0 = \dim \mathfrak{g}$.

$\gamma_{\bar{a}\bar{b}}$ is the Cartan–Killing metric.

The Dirac matrices are denoted by γ^a and they satisfy

$$\gamma^a \gamma^b + \gamma^b \gamma^a = 2\eta^{ab} I, \quad (49)$$

where η_{ab} is the Minkowski metric with signature $(-, +, \dots, +)$. γ^0 is anti-Hermitian and $\gamma^{a'}$ Hermitian.

The indices a, b are always raised or lowered with the help of the Minkowski metric, Greek indices with the help of the spacetime metric $\bar{g}_{\alpha\beta}$.

The γ^a act in

$$\mathbb{C}^{2^{\frac{n+1}{2}}}, \quad (50)$$

if n is odd and in

$$\mathbb{C}^{2^{\frac{n}{2}}} \oplus \mathbb{C}^{2^{\frac{n}{2}}}, \quad (51)$$

if n is even. In both cases, we simply refer to these spaces as

$$\mathbb{C}^{n_1}, \quad (52)$$

i.e., the spinor index A has a range of $1 \leq A \leq n_1$.

The color index I has a range of $1 \leq I \leq n_2$ and, hence, a spinor field ψ_A^I has values in

$$\mathbb{C}^{n_1} \otimes \mathbb{C}^{n_2}. \quad (53)$$

Finally, a Hermitian form $\langle \cdot, \cdot \rangle$ is anti-Hermitian in the first argument.

3. Spinor Fields

The Lagrangian of the spinor field is stated in (23). Here, $\psi = (\psi_A^I)$ is a multiplet of the spinors with spin $\frac{1}{2}$; A is the spinor index, $1 \leq A \leq n_1$, and I , $1 \leq I \leq n_2$, the color index. We shall also lower or raise the index I with the help of the Euclidean metric (δ_{IJ}) .

Let Γ_μ be the spinor connection

$$\Gamma_\mu = \frac{1}{4} \omega_\mu^b{}_a \gamma_b \gamma^a, \quad (54)$$

then the covariant derivative $D_\mu \psi$ is defined by

$$D_\mu \psi = \psi_{,\mu} + \Gamma_\mu \psi + A_\mu \psi. \quad (55)$$

Let (e_λ^b) be a n -bein, such that

$$\bar{g}_{\mu\lambda} = \eta_{ab} e_\mu^a e_\lambda^b, \quad (56)$$

where (η_{ab}) is the Minkowski metric, and let (E_a^μ) be its inverse

$$E_a^\mu = \eta_{ab} \bar{g}^{\mu\lambda} e_\lambda^b, \quad (57)$$

cf. [7] (p. 246).

The covariant derivative of E_a^α with respect to $(\bar{g}_{\alpha\beta})$ is then given by

$$E_{a;\mu}^\alpha = E_{a,\mu}^\alpha + \bar{\Gamma}_{\mu\beta}^\alpha E_a^\beta \quad (58)$$

and

$$\omega_\mu^b{}_a = E_{a;\mu}^\lambda e_\lambda^b = -E_a^\lambda e_{\lambda;\mu}^b, \quad (59)$$

hence, the spin connection Γ_μ can be expressed as

$$\Gamma_\mu = \frac{1}{4} \omega_\mu^b{}_a \gamma_b \gamma^a = \frac{1}{4} E_{a;\mu}^\lambda e_\lambda^b \gamma_b \gamma^a = -\frac{1}{4} E_a^\lambda e_{\lambda;\mu}^b \gamma_b \gamma^a. \quad (60)$$

We shall first show:

Lemma 2. Let $\bar{g}_{\alpha\beta}$ be a fixed spacetime metric that is split by the time function x^0 , then there exists an orthonormal frame (e_λ^a) , such that

$$e_k^0 = 0, \quad 1 \leq k \leq n, \quad (61)$$

and

$$e_{k;0}^{a'} = e_{,0}^{a'} - \bar{\Gamma}_{k0}^{\lambda} e_{\lambda}^{a'} = 0 \quad (62)$$

for all $1 \leq a' \leq n$ and $1 \leq k \leq n$.

Proof. Assume that

$$\bar{g}_{00} = -w^2, \quad (63)$$

then define the conformal metric

$$\tilde{g}_{\alpha\beta} = w^{-2} \bar{g}_{\alpha\beta}. \quad (64)$$

The curves

$$(\gamma^{\alpha}(t, x)) = (t, x^i), \quad x \in \mathcal{S}_0, \quad (65)$$

are then geodesics with respect to $\tilde{g}_{\alpha\beta}$. Let $(\hat{e}_{\lambda}^{a'})$, $1 \leq a' \leq n$, be an orthonormal frame in $T^{0,1}(\mathcal{S}_0) \hookrightarrow T^{0,1}(N)$, such that

$$\hat{e}_0^{a'} = 0 \quad \forall 1 \leq a' \leq n. \quad (66)$$

The $\hat{e}^{a'}$ depend on $x = (x^i) \in \mathcal{S}_0$. Let $(\tilde{e}_{\lambda}^{a'})(t, x)$ be the solutions of the flow equations

$$\begin{aligned} \frac{D}{dt} \tilde{e}_{\lambda}^{a'} &= 0, \\ \tilde{e}_{\lambda}^{a'}(0, x) &= \hat{e}_{\lambda}^{a'}(x), \end{aligned} \quad (67)$$

i.e., we parallel transport $\hat{e}^{a'}$ along the geodesics. Setting

$$(\tilde{e}_{\lambda}^0) = (1, 0, \dots, 0) \quad (68)$$

the (\tilde{e}_{λ}^a) are then an orthonormal frame of 1-forms in $(N, \tilde{g}_{\alpha\beta})$ such that the \tilde{e}^a satisfy

$$\tilde{e}_{\lambda;0}^a = 0 \quad \forall 0 \leq a \leq n, \quad (69)$$

where we indicate covariant differentiation with respect to $\tilde{g}_{\alpha\beta}$ by a colon.

Define e_{λ}^a by

$$e_{\lambda}^a = w \tilde{e}_{\lambda}^a, \quad (70)$$

then the e_{λ}^a are orthonormal frames in $(N, \bar{g}_{\alpha\beta})$. The Christoffel symbols $\bar{\Gamma}_{\alpha\beta}^{\gamma}$ resp. $\tilde{\Gamma}_{\alpha\beta}^{\gamma}$ are related by the formula

$$\bar{\Gamma}_{\alpha\beta}^{\gamma} = \tilde{\Gamma}_{\alpha\beta}^{\gamma} - w^{-1} w_{\alpha} \delta_{\beta}^{\gamma} + w^{-1} w_{\beta} \delta_{\alpha}^{\gamma} - w^{-1} \tilde{w}^{\gamma} \tilde{g}_{\alpha\beta}, \quad (71)$$

where

$$\tilde{w}^{\gamma} = \tilde{g}^{\gamma\lambda} w_{\lambda}. \quad (72)$$

In view of (69), we then infer

$$0 = \tilde{e}_{j;0}^{a'} = \dot{\tilde{e}}_j^{a'} - \tilde{\Gamma}_{0j}^k \tilde{e}_k^{a'} \quad (73)$$

and we deduce further

$$\begin{aligned} e_{j;0}^{a'} &= \dot{w} \tilde{e}_j^{a'} + w \dot{\tilde{e}}_j^{a'} - \bar{\Gamma}_{0j}^k w \tilde{e}_k^{a'} \\ &= \dot{w} \tilde{e}_j^{a'} + \tilde{\Gamma}_{0j}^k w \tilde{e}_k^{a'} - \bar{\Gamma}_{0j}^k w \tilde{e}_k^{a'} \\ &= 0 \end{aligned} \quad (74)$$

because of (71). \square

Subsequently, we shall always use these particular orthonormal frames.

We are now able to simplify the expressions for the spin connections

$$\Gamma_\mu = -\frac{1}{4}E_a^\lambda e_{\lambda;\mu}^b \gamma_a \gamma^b. \quad (75)$$

We have

$$\begin{aligned} 4\Gamma_0 &= -E_a^\lambda e_{\lambda;0}^b \gamma_b \gamma^a \\ &= -E_a^\lambda e_{\lambda;0}^0 \gamma_0 \gamma^a - E_a^\lambda e_{\lambda;0}^{b'} \gamma_{b'} \gamma^a \\ &= -E_0^0 e_{0;0}^0 \gamma_0 \gamma^0 - E_{a'}^i e_{i;0}^0 \gamma_0 \gamma^{a'} - E_0^0 e_{0;0}^{b'} \gamma_{b'} \gamma^0 - E_{a'}^i e_{i;0}^{b'} \gamma_{b'} \gamma^{a'} \\ &= -E_{a'}^i e_{i;0}^0 \gamma_0 \gamma^{a'} - E_0^0 e_{0;0}^{b'} \gamma_{b'} \gamma^0 \end{aligned} \quad (76)$$

in view of Lemma 2 and the fact that

$$e_{0;0}^0 = 0. \quad (77)$$

The matrices $\gamma_0 \gamma^{a'}$ and $\gamma_{b'} \gamma^0$ are Hermitian, since γ^0 is anti-Hermitian, $\gamma^{a'}$ Hermitian, and there holds

$$\gamma_0 \gamma^{a'} = -\gamma^{a'} \gamma_0. \quad (78)$$

Hence, the quadratic form

$$\bar{\psi} E_a^0 \gamma^a \Gamma_0 \psi = -i E_0^0 \bar{\psi} \Gamma_0 \psi \quad (79)$$

is imaginary and will be eliminated by adding its complex conjugate. Γ_0 can therefore be ignored, which we shall indicate by writing

$$\Gamma_0 \simeq 0. \quad (80)$$

A similar notation should apply to other terms that will be canceled when adding the complex conjugates.

Let us consider Γ_k :

$$\begin{aligned} 4\Gamma_k &= -E_a^\lambda e_{\lambda;k}^b \gamma_b \gamma^a \\ &= -E_a^\lambda e_{\lambda;k}^0 \gamma_0 \gamma^a - E_a^\lambda e_{\lambda;k}^{b'} \gamma_{b'} \gamma^a \\ &= -E_0^0 e_{0;k}^0 \gamma_0 \gamma^0 - E_{a'}^i e_{i;k}^0 \gamma_0 \gamma^{a'} - E_0^0 e_{0;k}^{b'} \gamma_{b'} \gamma^0 - E_{a'}^i e_{i;k}^{b'} \gamma_{b'} \gamma^{a'}. \end{aligned} \quad (81)$$

The first term on the right-hand side vanishes, since

$$e_{0;k}^0 = w_k - \bar{\Gamma}_{0k}^0 w = 0. \quad (82)$$

Furthermore, there holds

$$e_{i;k}^0 = -\bar{\Gamma}_{ik}^0 w = -\frac{1}{2} \dot{g}_{ik} w^{-1} \quad (83)$$

and

$$e_{0;k}^{b'} = -\bar{\Gamma}_{0k}^{b'} w = -\frac{1}{2} g^{lj} \dot{g}_{kl} e_j^{b'}, \quad (84)$$

yielding

$$\begin{aligned} 4\Gamma_k &= \frac{1}{2} \dot{g}_{ik} w^{-1} E_{a'}^i \gamma_0 \gamma^{a'} + \frac{1}{2} w^{-1} g^{lj} \dot{g}_{kl} e_i^{b'} \gamma_{b'} \gamma^0 - E_{a'}^i e_{i;k}^{b'} \gamma_{b'} \gamma^{a'} \\ &= w^{-1} \dot{g}_{ik} E_{a'}^i \gamma_0 \gamma^{a'} - E_{a'}^i e_{i;k}^{b'} \gamma_{b'} \gamma^{a'}, \end{aligned} \quad (85)$$

since

$$\gamma_0 \gamma^{a'} = -\gamma^{a'} \gamma_0. \quad (86)$$

The first term on the right-hand side of (85) has to be eliminated because of the presence of \dot{g}_{ik} . To achieve this, fix a Riemannian metric $\rho_{ij} = \rho_{ij}(x) \in T^{0,2}(\mathcal{S}_0)$, and define the function φ by

$$\varphi = \sqrt{\frac{\det g_{ij}}{\det \rho_{ij}}} \quad (87)$$

and the spinors $\chi = (\chi_A^i)$ by

$$\chi = \sqrt{\varphi} \psi, \quad (88)$$

then

$$\dot{\chi} = \sqrt{\varphi} \dot{\psi} + \frac{1}{4} \dot{g}^{ij} \dot{g}_{ij} \chi \quad (89)$$

and

$$\chi_{,k} = \frac{1}{2} \varphi_k \varphi^{-1/2} \chi + \sqrt{\varphi} \psi_{,k}. \quad (90)$$

Looking at the real part of the quadratic form

$$i \tilde{\chi} E_{a'}^k \gamma^{a'} \chi_{,k} \quad (91)$$

we deduce that

$$\chi_{,k} \simeq \sqrt{\varphi} \psi_{,k}. \quad (92)$$

Moreover, we infer

$$\begin{aligned} i \tilde{\psi} E_{c'}^k \gamma^{c'} \Gamma_k \psi &= i \tilde{\psi} E_{c'}^k \gamma^0 \gamma^{c'} \Gamma_k \psi \\ &= \frac{1}{4} i \tilde{\psi} E_{c'}^k E_{a'}^j w^{-1} \dot{g}_{jk} \gamma^0 \gamma^{c'} \gamma_0 \gamma^{a'} \psi \\ &\quad - \frac{1}{4} i \tilde{\psi} E_{c'}^k E_{a'}^j e_{jk}^{b'} \gamma^0 \gamma^{c'} \gamma_{b'} \gamma^{a'} \psi. \end{aligned} \quad (93)$$

We now observe that

$$\gamma^0 \gamma^{c'} \gamma_0 \gamma^{a'} = -\gamma^0 \gamma_0 \gamma^{c'} \gamma^{a'} = -\gamma^{c'} \gamma^{a'}, \quad (94)$$

hence,

$$E_{c'}^k E_{a'}^j \gamma^0 \gamma^{c'} \gamma_0 \gamma^{a'} = -E_{c'}^k E_{a'}^j \gamma^{c'} \gamma^{a'} = -g^{jk} \quad (95)$$

and we conclude

$$\begin{aligned} i \tilde{\psi} E_c^\mu \gamma^c D_\mu \psi \varphi &\simeq -i \tilde{\chi} \dot{\chi} w^{-1} \\ &\quad + i \tilde{\chi} E_{c'}^k \gamma^0 \gamma^{c'} \{ \chi_{,k} - \frac{1}{4} E_{a'}^j e_{jk}^{b'} \gamma_{b'} \gamma^{a'} \chi + A_k \chi \} \end{aligned} \quad (96)$$

Remark 2. The term in the braces is the covariant derivative of χ with respect to the spin connection $\tilde{\Gamma}_k$

$$\tilde{\Gamma}_{ka'}^{b'} = \frac{1}{4} \tilde{\omega}_{ka'}^{b'} = -\frac{1}{4} E_{a'}^j e_{jk}^{b'} \gamma_{b'} \gamma^{a'} \quad (97)$$

and the Yang–Mills connection (A_μ) satisfying $A_0 = 0$, such that

$$\tilde{D}_k \chi = \chi_{,k} + \tilde{\Gamma}_k \chi + A_k \chi. \quad (98)$$

The gauge transformations for both the Yang–Mills connection as well as for the spin connection do not depend on x^0 but only on $x \in \mathcal{S}_0$. In case of the Yang–Mills connection, this has already been proved in [8] (Lemma 2.6), while the proof for the spin connection $\tilde{\Gamma}_k$ follows from (97) and (85) if we only consider Lorentzian metrics of the form

$$d\bar{s}^2 = -dt^2 + g_{ij}(x) dx^i dx^j \quad (99)$$

in a product manifold $N = I \times \mathcal{S}_0$, as will be the case after the quantization of the Dirac field.

Summarizing the preceding results, we obtain:

Lemma 3. *The Dirac Lagrangian can be expressed in the form*

$$L_D = \frac{i}{2}(\bar{\chi}_I \dot{\chi}^I - \dot{\bar{\chi}}^I \chi_I) w^{-1} \varphi^{-1} + m i \bar{\chi}_I \gamma^0 \chi^I \varphi^{-1} - \frac{i}{2} \{ \bar{\chi}_I \gamma^0 E_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I - \overline{\bar{\chi}_I \gamma^0 E_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I} \} \varphi^{-1}, \quad (100)$$

where χ and \tilde{D}_k are defined in (88) resp. (98).

4. Quantization of the Lagrangian

We consider the functional

$$J = \alpha_N^{-1} \int_{\tilde{\Omega}} (\bar{R} - 2\Lambda) - \int_{\tilde{\Omega}} \frac{1}{4} \gamma_{\bar{a}\bar{b}} \bar{g}^{\mu\rho_2} \bar{g}^{\lambda\rho_1} F_{\mu\rho_1}^{\bar{a}} F_{\rho_2\lambda}^{\bar{b}} - \int_{\tilde{\Omega}} \{ \frac{1}{2} \bar{g}^{\mu\lambda} \gamma_{\bar{a}\bar{b}} \Phi_{\mu}^{\bar{a}} \bar{\Phi}_{\lambda}^{\bar{b}} + V(\Phi) \} + \int_{\tilde{\Omega}} \{ \frac{1}{2} [\bar{\psi}_I E_a^{\mu} \gamma^a (D_{\mu} \psi)^I + \overline{\bar{\psi}_I E_a^{\mu} \gamma^a (D_{\mu} \psi)^I}] + m \bar{\psi}_I \psi^I \}, \quad (101)$$

where α_N is a positive coupling constant and $\tilde{\Omega} \in N$.

We use the action principle that, for an arbitrary $\tilde{\Omega}$ as above, a solution (A, Φ, ψ, \bar{g}) should be a stationary point of the functional with respect to compact variations. This principle requires no additional surface terms for the functional.

As we proved in [1], we may only consider metrics $\bar{g}_{\alpha\beta}$ that split with respect to some fixed globally defined time function x^0 , such that

$$d\bar{s}^2 = -w^2 (dx^0)^2 + g_{ij} dx^i dx^j \quad (102)$$

where $g(x^0, \cdot)$ are Riemannian metrics in \mathcal{S}_0 ,

$$\mathcal{S}_0 = \{x^0 = 0\}. \quad (103)$$

The first functional on the right-hand side of (101) can be written in the form

$$\alpha_N^{-1} \int_a^b \int_{\Omega} \{ \frac{1}{4} G^{ij,kl} \dot{g}_{ij} \dot{g}_{kl} w^{-2} + R - 2\Lambda \} w \varphi, \quad (104)$$

where

$$G^{ij,kl} = \frac{1}{2} \{ g^{ik} g^{jl} + g^{il} g^{jk} \} - g^{ij} g^{kl} \quad (105)$$

is the DeWitt metric,

$$(g^{ij}) = (g_{ij})^{-1}, \quad (106)$$

R the scalar curvature of the slices

$$\{x^0 = t\} \quad (107)$$

with respect to the metric $g_{ij}(t, \cdot)$, and where we also assumed that $\tilde{\Omega}$ is a cylinder

$$\tilde{\Omega} = (a, b) \times \Omega, \quad \Omega \in \mathcal{S}_0, \quad (108)$$

such that $\tilde{\Omega} \subset U_k$ for some $k \in \mathbb{N}$, where the U_k are special coordinate patches of N , such that there exists a local trivialization in U_k with the properties that there is a fixed Yang–Mills connection

$$\bar{A} = (\bar{A}_{\mu}^{\bar{a}}) = f_{\bar{a}} \bar{A}_{\mu}^{\bar{a}} dx^{\mu} \quad (109)$$

satisfying

$$\bar{A}_0^{\bar{a}} = 0 \quad \text{in } U_k, \quad (110)$$

cf. [8] (Lemma 2.5). We may then assume that the Yang–Mills connections $A = (A_\mu^{\bar{a}})$ are of the form

$$A_\mu^{\bar{a}}(t, x) = \bar{A}_\mu^{\bar{a}}(0, x) + \tilde{A}_\mu^{\bar{a}}(t, x), \quad (111)$$

where $(\tilde{A}_\mu^{\bar{a}})$ is a tensor, see [8] (Section 2).

The Riemannian metrics $g_{ij}(t, \cdot)$ are elements of the bundle $T^{0,2}(\mathcal{S}_0)$. Denote by E the fiber bundle with base \mathcal{S}_0 where the fibers $F(x)$ consist of the Riemannian metrics (g_{ij}) . We shall consider each fiber to be a Lorentzian manifold equipped with the DeWitt metric. Each fiber F has the dimension

$$\dim F = \frac{n(n+1)}{2} \equiv m+1. \quad (112)$$

Let (ξ^r) , $0 \leq r \leq m$, be coordinates for a local trivialization, such that

$$g_{ij}(x, \xi^r) \quad (113)$$

is a local embedding. The DeWitt metric is then expressed as

$$G_{rs} = G^{ijkl} g_{ij,r} g_{kl,s}, \quad (114)$$

where a comma indicates partial differentiation. In the new coordinate system, the curves

$$t \rightarrow g_{ij}(t, x) \quad (115)$$

can be written in the form

$$t \rightarrow \xi^r(t, x) \quad (116)$$

and we infer

$$G^{ijkl} \dot{g}_{ij} \dot{g}_{kl} = G_{rs} \dot{\xi}^r \dot{\xi}^s. \quad (117)$$

Hence, we can express (104) as

$$J = \int_a^b \int_\Omega \alpha_n^{-1} \{ \frac{1}{4} G_{rs} \dot{\xi}^r \dot{\xi}^s w^{-1} \varphi + (R - 2\Lambda) w \varphi \}, \quad (118)$$

where we now refrain from writing down the density $\sqrt{\rho}$ explicitly, since it does not depend on (g_{ij}) and, therefore, should not be part of the Legendre transformation. Here, we follow Mackey's advice in [9] (p. 94) to always consider rectangular coordinates when applying canonical quantization, which can be rephrased that the Hamiltonian has to be a coordinate invariant, hence no densities are allowed.

Denoting the Lagrangian function in (118) by L , we define

$$\pi_r = \frac{\partial L}{\partial \dot{\xi}^r} = \varphi G_{rs} \frac{1}{2\alpha_N} \dot{\xi}^s w^{-1} \quad (119)$$

and we obtain for the Hamiltonian function \hat{H}_G

$$\begin{aligned} \hat{H}_G &= \dot{\xi}^r \frac{\partial L}{\partial \dot{\xi}^r} - L \\ &= \varphi G_{rs} \left(\frac{1}{2\alpha_N} \dot{\xi}^r w^{-1} \right) \left(\frac{1}{2\alpha_N} \dot{\xi}^s w^{-1} \right) w \alpha_N - \alpha_N^{-1} (R - 2\Lambda) \varphi w \\ &= \varphi^{-1} G^{rs} \pi_r \pi_s w \alpha_N - \alpha_N^{-1} (R - 2\Lambda) \varphi w \\ &\equiv H_G w, \end{aligned} \quad (120)$$

where G^{rs} is the inverse metric. Hence,

$$H_G = \alpha_N \varphi^{-1} G^{rs} \pi_r \pi_s - \alpha_N^{-1} (R - 2\Lambda) \varphi \quad (121)$$

is the Hamiltonian that will enter the Hamilton constraint, for details see [6] (Chapter 1.4).

Let us recall that the fibers F can be considered Lorentzian manifolds, even globally hyperbolic manifolds, equipped with the DeWitt metric $(\varphi G^{ij,kl})$, where φ is a time function, cf. [6] (Theorem 1.4.2). In the fibers, we can introduce new coordinates, $(\zeta^a) = (\zeta^0, \zeta^A) \equiv (t, \zeta^A)$, $0 \leq a \leq m$, and $1 \leq A \leq m$, such that

$$t = \sqrt{\varphi} \quad (122)$$

and (ζ^A) are coordinates for the hypersurface

$$M = \{\varphi = 1\} = \{\zeta^0 = 1\}. \quad (123)$$

The Lorentzian metric in the fibers can then be expressed in the form

$$ds^2 = -\frac{16(n-1)}{n} dt^2 + t^2 G_{AB} d\zeta^A d\zeta^B, \quad (124)$$

where (G_{AB}) is a Riemannian metric on M , which is independent of t . When we work in a local trivialization of the bundle E , the coordinates (ζ^A) are independent of x . The time coordinate t is also independent of x , cf. [1] (Lemma 1.8). Moreover, the fiber elements (g_{ij}) can be expressed in the form

$$g_{ij} = t^{\frac{4}{n}} \sigma_{ij}, \quad (125)$$

where (σ_{ij}) is an element of M , i.e.,

$$t(\sigma_{ij}) = 1, \quad (126)$$

or equivalently,

$$\det \sigma_{ij} = \det \rho_{ij}. \quad (127)$$

Next, let us look at the Yang–Mills Lagrangian, which can be expressed as

$$L_{YM} = \frac{1}{2} \gamma_{\bar{a}\bar{b}} g^{ij} \tilde{A}_{i,0}^{\bar{a}} \tilde{A}_{j,0}^{\bar{b}} w^{-1} \varphi - \frac{1}{4} F_{ij} F^{ij} w \varphi. \quad (128)$$

Let E_0 be the adjoint bundle

$$E_0 = (S_0, \mathfrak{g}, \pi, \text{Ad}(\mathcal{G})) \quad (129)$$

with base space S_0 , where the gauge transformations only depend on the spatial variables $x = (x^i)$. Then the mappings $t \rightarrow \tilde{A}_i^{\bar{a}}(t, \cdot)$ can be looked at as curves in $T^{1,0}(E_0) \otimes T^{0,1}(S_0)$, where the fibers of $T^{1,0}(E_0) \otimes T^{0,1}(S_0)$ are the tensor products

$$\mathfrak{g} \otimes T_x^{0,1}(S_0), \quad x \in S_0, \quad (130)$$

which are vector spaces equipped with the metric

$$\gamma_{\bar{a}\bar{b}} \otimes g^{ij}. \quad (131)$$

For our purposes, it is more convenient to consider the fibers to be Riemannian manifolds endowed with the above metric. Let (ζ^p) , $1 \leq p \leq n_1 n$, where $n_0 = \dim \mathfrak{g}$, be local coordinates and

$$(\zeta^p) \rightarrow \tilde{A}_i^{\bar{a}}(\zeta^p) \equiv \tilde{A}(\zeta) \quad (132)$$

be a local embedding, then the metric has the coefficients

$$G_{pq} = \langle \tilde{A}_p, \tilde{A}_q \rangle = \gamma_{\bar{a}\bar{b}} g^{ij} \tilde{A}_{i,p}^{\bar{a}} \tilde{A}_{j,q}^{\bar{b}}. \quad (133)$$

Hence, the Lagrangian L_{YM} in (128) can be expressed in the form

$$L_{YM} = \frac{1}{2} G_{pq} \dot{\zeta}^p \dot{\zeta}^q w^{-1} \varphi - \frac{1}{4} F_{ij} F^{ij} w \varphi \quad (134)$$

and we deduce

$$\tilde{\pi}_p = \frac{\partial L_{YM}}{\partial \dot{\zeta}^p} = G_{pq} \dot{\zeta}^q w^{-1} \varphi \quad (135)$$

yielding the Hamilton function

$$\begin{aligned} \hat{H}_{YM} &= \pi_p \dot{\zeta}^p - L_{YM} \\ &= \frac{1}{2} G_{pq} (\dot{\zeta}^p w^{-1} \varphi) (\dot{\zeta}^q w^{-1} \varphi) w \varphi^{-1} + \frac{1}{4} F_{ij} F^{ij} w \varphi \\ &= \frac{1}{2} G^{pq} \tilde{\pi}_p \tilde{\pi}_q w \varphi^{-1} + \frac{1}{4} F_{ij} F^{ij} w \varphi \\ &\equiv H_{YM} w. \end{aligned} \quad (136)$$

Thus, after introducing a normal Gaussian coordinate system, such that $w = 1$, the Hamiltonian that will enter the Hamilton constraint equation is

$$H_{YM} = \frac{1}{2} \varphi^{-1} G^{pq} \tilde{\pi}_p \tilde{\pi}_q + \frac{1}{4} F_{ij} F^{ij} \varphi. \quad (137)$$

Combining, now, (122), (125) and (133) we infer that the Yang–Mills Hamiltonian can be expressed as

$$H_{YM} = t^{\frac{4}{n}-2} \tilde{G}^{pq} \tilde{\pi}_p \tilde{\pi}_q + \frac{1}{4} F_{ij} F^{ij} t^{2-\frac{8}{n}}, \quad (138)$$

where the indices in the last term are raised with respect to the metric σ_{ij} , i.e.,

$$F^{ij} = \sigma^{ik} \sigma^{jl} F_{kl}. \quad (139)$$

In the case of $n = 3$, the exponents of t in (138) are equal

$$\frac{4}{3} - 2 = 2 - \frac{8}{3} = -\frac{2}{3} \quad (140)$$

and we can write

$$\begin{aligned} H_{YM} &= t^{-\frac{2}{3}} \{ \tilde{G}^{pq} \tilde{\pi}_p \tilde{\pi}_q + \frac{1}{4} F_{ij} F^{ij} \} \\ &\equiv t^{-\frac{2}{3}} \tilde{H}_{YM}. \end{aligned} \quad (141)$$

Moreover, if (σ_{ij}) as well as (ρ_{ij}) are equal to the Euclidean metric (δ_{ij}) , then the quantization of \tilde{H}_{YM} would be achieved by known methods of QFT.

Hence, we shall attempt to express the Hamiltonians of the other physical forces, such as the Dirac and Higgs Hamiltonians, when evaluated for

$$\sigma_{ij} = \rho_{ij} = \delta_{ij} \quad (142)$$

and in the case of $n = 3$ in the form

$$H_D = t^{-\frac{2}{3}} \tilde{H}_D \quad (143)$$

resp.

$$H_H = t^{-\frac{2}{3}} \tilde{H}_H \quad (144)$$

such that the quantization of the spatial Hamiltonian

$$\tilde{H}_{YM} + \tilde{H}_D + \tilde{H}_H \quad (145)$$

would be well known, and in the end, all spatial Hamiltonians of the standard model could be incorporated.

Let us first consider the Dirac Hamiltonian. In the Dirac Lagrangian L_D , defined in Equation (100) on page 11, the volume density \sqrt{g} is missing, i.e., in order to define the Hamiltonian, we have to multiply the Lagrangian with \sqrt{g} , or, since we work with functions instead of densities, we have to multiply the Lagrangian with φ .

In addition, we shall also consider—at least locally—a normal Gaussian coordinate system, such that $w = 1$. Then, the final Dirac Lagrangian has the form

$$L_D = \frac{i}{2}(\bar{\chi}_I \dot{\chi}^I - \dot{\bar{\chi}}^I \chi_I) + mi\bar{\chi}_I \gamma^0 \chi^I - \frac{i}{2}\{\bar{\chi}_I \gamma^0 E_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I - \overline{\bar{\chi}_I \gamma^0 E_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I}\}, \quad (146)$$

The spinorial variables χ_A^I are anti-commuting Grassmann variables. They are elements of a Grassmann algebra with involution, where the involution corresponds to the complex conjugation and will be denoted by a bar.

The χ_A^I are complex variables and we define the real resp. imaginary parts as

$$\xi_A^I = \frac{1}{\sqrt{2}}(\chi_A^I + \bar{\chi}_A^I) \quad (147)$$

resp.

$$\eta_A^I = \frac{1}{\sqrt{2}i}(\chi_A^I - \bar{\chi}_A^I). \quad (148)$$

Then,

$$\chi_A^I = \frac{1}{\sqrt{2}}(\xi_A^I + i\eta_A^I) \quad (149)$$

and

$$\bar{\chi}_A^I = \frac{1}{\sqrt{2}}(\xi_A^I - i\eta_A^I). \quad (150)$$

With these definitions, we obtain

$$\frac{i}{2}(\bar{\chi}_I \dot{\chi}^I - \dot{\bar{\chi}}^I \chi_I) = \frac{i}{2}(\xi_I^A \dot{\xi}_A^I + \eta_I^A \dot{\eta}_A^I). \quad (151)$$

Casalbuoni quantized the Bose–Fermi system in [10] (section 4), the results of which can be applied to spin $\frac{1}{2}$ fermions. The Lagrangian in [10] is the same as the main part our Lagrangian in (146) on page 15, and the left derivative is used in that paper; hence, we use left derivatives as well such that the conjugate momenta of the odd variables are, e.g.,

$$\pi_I^A = \frac{\partial L}{\partial \dot{\xi}_I^A} = -\frac{i}{2}\xi_I^A, \quad (152)$$

and, thus, the conclusions in [10] can be applied.

The Lagrangian has been expressed in real variables—at least the important part of it—and it follows that the odd variables ξ_A^I, η_A^I satisfy, after introducing anti-commutative Dirac brackets as in [10] (equ. (4.11)),

$$\{\xi_I^A, \xi_B^I\}_+^* = -i\delta_I^J \delta_B^A, \quad (153)$$

$$\{\eta_I^A, \eta_B^I\}_+^* = -i\delta_I^J \delta_B^A, \quad (154)$$

and

$$\{\xi_I^A, \eta_B^I\}_+^* = 0, \quad (155)$$

cf. [10] (equ. (4.19)).

In view of (149), (150) we then derive

$$\{\bar{\chi}_I^A, \chi_B^I\}_+^* = -i\delta_I^J \delta_B^A, \quad (156)$$

where $\bar{\chi}_I^A$ are the conjugate momenta.

Canonical quantization—with $\hbar = 1$ —then requires that the corresponding operators $\hat{\chi}_A^I, \hat{\chi}_J^B$ satisfy the anti-commutative rules

$$[\hat{\chi}_A^I, \hat{\chi}_J^B]_+ = i\{\chi_A^I, \bar{\chi}_J^B\}_+^* = \delta_J^I \delta_A^B \quad (157)$$

and

$$[\hat{\chi}_I^A, \hat{\chi}_J^B]_+ = [\hat{\chi}_A^I, \hat{\chi}_B^J]_+ = 0, \quad (158)$$

cf. [11] (equ. (3.10)) and [10] (equ. (5.17)).

From (146), we then deduce that the spinorial Hamilton function is equal to

$$H_D = \frac{i}{2} \{ \bar{\chi}_I \gamma^0 E_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I - \overline{\bar{\chi}_I \gamma^0 E_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I} \} - mi \bar{\chi}_I \gamma^0 \chi^I. \quad (159)$$

When we attempt to quantize this Hamilton function, then the vielbein $e_k^{a'}$ and its inverse $E_{a'}^k$ will correspond to a given element $g_{ij}(x)$ in the fiber F , which can be expressed as in (125), and we deduce that the vielbein

$$\tilde{e}_k^{a'} = t^{-\frac{2}{n}} e_k^{a'} \quad (160)$$

and its inverse

$$\tilde{E}_{a'}^k = t^{\frac{2}{n}} E_{a'}^k \quad (161)$$

correspond to the metric σ_{ij} . Furthermore, the covariant derivative $\tilde{D}_k \chi^I$ is independent of t , in view of (97) and (98) on page 10. Thus, the Hamilton function H_D can be expressed as

$$H_D = t^{-\frac{2}{3}} \left(\frac{i}{2} \{ \bar{\chi}_I \gamma^0 \tilde{E}_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I - \overline{\bar{\chi}_I \gamma^0 \tilde{E}_{a'}^k \gamma^{a'} \tilde{D}_k \chi^I} \} \right) - mi \bar{\chi}_I \gamma^0 \chi^I, \quad (162)$$

i.e., the main part already has the form that we looked for in (143), provided $n = 3$, only the mass term spoils the necessary configuration. To overcome this setback, we either have to omit the mass term or modify it by multiplying the mass term in (23) on page 3 with the factor

$$\varphi^{-\frac{1}{n}}, \quad (163)$$

where φ is defined in (87) on page 10. Note that $\varphi = 1$ if

$$g_{ij} = \rho_{ij} = \delta_{ij} \quad (164)$$

as is the case in QFT. Either by omitting or by modifying the mass term, the Dirac Hamilton function can be expressed in the required form

$$H_D = t^{-\frac{2}{3}} \tilde{H}_D, \quad (165)$$

where the underlying Riemannian metric is σ_{ij} , provided $n = 3$.

The remaining Hamiltonian is the Hamiltonian of the Higgs field. The Higgs Lagrangian is defined by

$$L_H = -\frac{1}{2} \delta^{\alpha\beta} \gamma_{ab} \Phi_\alpha^a \Phi_\beta^b - V(\Phi), \quad (166)$$

where V is a smooth potential. We assume that in a local coordinate system Φ has real coefficients. The covariant derivatives of Φ are defined by a connection $A = (A_\mu^a)$ in E_0

$$\Phi_\mu^a = \Phi_{,\mu}^a + f_{cb}^a A_\mu^c \Phi^b. \quad (167)$$

As in the preceding section, we work in a local trivialization of E_0 using the temporal gauge, i.e.,

$$A_0^a = 0, \quad (168)$$

hence, we conclude

$$\Phi_0^a = \Phi_{,0}^a. \quad (169)$$

Expressing the density g as in (87) on page 10, we obtain Lagrangian

$$L_H = \frac{1}{2}\gamma_{ab}\Phi_{,0}^a\Phi_{,0}^b\varphi - \frac{1}{2}g^{ij}\gamma_{ab}\Phi_i^a\Phi_j^b\varphi - V(\Phi)\varphi, \quad (170)$$

where, again, we use local coordinates, such that $w = 1$. In order to apply our approach, outlined in (144), we have to modify the Lagrangian. Instead of the above Lagrangian, we have to consider

$$L_{Hmod} = \{\frac{1}{2}\gamma_{ab}\Phi_{,0}^a\Phi_{,0}^b - \frac{1}{2}g^{ij}\gamma_{ab}\Phi_i^a\Phi_j^b\}\varphi^{1+\gamma_1} - V(\Phi)\varphi^{1+\gamma_2}. \quad (171)$$

Let us define

$$p_a = \frac{\partial L_H}{\partial \dot{\Phi}^a}, \quad \dot{\Phi}^a = \Phi_{,0}^a, \quad (172)$$

then we obtain the Hamilton function

$$\begin{aligned} H_{Hmod} &= p_a \dot{\Phi}^a - L_H \\ &= \frac{1}{2}\gamma^{ab}p_ap_b\varphi^{-(1+\gamma_1)} + \frac{1}{2}g^{ij}\gamma_{ab}\Phi_i^a\Phi_j^b\varphi^{1+\gamma_1} + V(\Phi)\varphi^{1+\gamma_2}. \end{aligned} \quad (173)$$

After quantization, the g_{ij} are elements of the fiber F , i.e.,

$$g_{ij} = t^{\frac{4}{n}}\sigma_{ij}. \quad (174)$$

If $n = 3$, then γ_1 has to be chosen, such that

$$-2(1+\gamma_1) = -\frac{4}{3} + 2(1+\gamma_1) = -\frac{2}{3} \quad (175)$$

which is the case if

$$\gamma_1 = -\frac{2}{3}. \quad (176)$$

For γ_2 , we obtain

$$2(1+\gamma_2) = -\frac{2}{3} \quad (177)$$

yielding

$$\gamma_2 = -\frac{4}{3}. \quad (178)$$

Thus, the Hamilton function of the modified Higgs field has the required form

$$H_{Hmod} = t^{-\frac{2}{3}}\tilde{H}_{Hmod}, \quad (179)$$

where

$$\tilde{H}_{Hmod} = \frac{1}{2}\gamma^{ab}p_ap_b + \frac{1}{2}\sigma^{ij}\gamma_{ab}\Phi_i^a\Phi_j^b + V(\Phi) \quad (180)$$

is a standard Hamiltonian of a Higgs field in QFT by choosing $\sigma_{ij} = \delta_{ij}$ and $\Phi, V(\Phi)$ as well as the Yang–Mills connection appropriately.

Combining the four Hamilton functions in (120), (138), (179) and (162), the Hamilton constraint has the form

$$\begin{aligned} H &= H_G + H_{YM} + H_H + H_D \\ &= H_G + t^{-\frac{2}{3}}(\tilde{H}_{YM} + \tilde{H}_H + \tilde{H}_D) \\ &\equiv H_G + t^{-\frac{2}{3}}\tilde{H}_{SM} = 0, \end{aligned} \quad (181)$$

where we omit the subscript *mod* and where *SM* refers to the fields of the standard model or to a corresponding subset of fields.

The Hamiltonian

$$H_G = \alpha_N \varphi^{-1} G^{rs} \pi_r \pi_s - \alpha_N^{-1} (R - 2\Lambda) \varphi \quad (182)$$

we quantize, as in our former papers [1,12], to obtain

$$H_G = -\alpha_N \Delta - \alpha_N^{-1} R t^2 + 2\alpha_N^{-1} \Lambda t^2, \quad (183)$$

where the Laplacian is the Laplacian of the metric (124) acting in the fibers F of E . The Laplacian acts on smooth functions u of the form $u = u(g_{ij})$. Choosing the Gaussian coordinate system $(\xi^a) = (t, \xi^A)$, such that the fiber metric has form as in (124), then, the hyperbolic term $-\Delta u$ can be expressed as

$$-\Delta u = \frac{n}{16(n-1)} t^{-m} \frac{\partial}{\partial t} (t^m \frac{\partial u}{\partial t}) - t^{-2} \bar{\Delta} u, \quad (184)$$

where $\bar{\Delta}$ is the Laplacian of the hypersurface

$$M = \{t = 1\}. \quad (185)$$

Using the separation of variables we consider functions u which are products

$$u(t, \xi^A) = w(t) v(\xi^A), \quad (186)$$

where v is a spatial eigenfunction, or eigendistribution, of the Laplacian $\bar{\Delta}$

$$-\bar{\Delta} v = \lambda v. \quad (187)$$

The hypersurface

$$M = \{\varphi = 1\} \quad (188)$$

can be considered a subbundle of E , where each fiber $M(x)$ is a hypersurface in the fiber $F(x)$ of E . We shall use the same notation M for the subbundle as well as for the hypersurface, and in general, we shall omit the reference to the base point $x \in \mathcal{S}_0$. Furthermore, we specify the metric $\rho_{ij} \in T^{0,2}(\mathcal{S}_0)$, which we used to define φ , to be equal to the Euclidean metric, such that in Euclidean coordinates

$$\varphi^2 = \frac{\det g_{ij}}{\det \delta_{ij}} = \det g_{ij}. \quad (189)$$

Then, it is well-known that each $M(x)$ with the induced metric (G_{AB}) is a symmetric space, namely, it is isometric to the coset space

$$G/K = SL(n, \mathbb{R})/SO(n), \quad (190)$$

cf. [13] (equ. (5.17), p. 1123) and [14] (p. 3). The eigenfunctions in symmetric spaces, and especially of the coset space in (190), are well-known; they are the so-called *spherical functions*. One can also define a Fourier transformation for functions in $L^2(G/K)$ and prove a Plancherel formula, similar to the Euclidean case, cf. [15] (Chapter III). Moreover, similar to the Euclidean case, we shall use the Fourier kernel to define the eigenfunctions or eigendistributions, cf. [3] (Section 5).

Let

$$G = NAK \quad (191)$$

be an Iwasawa decomposition of G , where N is the subgroup of unit upper triangle matrices, A is the abelian subgroup of the diagonal matrices with strictly positive diagonal components and $K = SO(n)$. The corresponding Lie algebras are denoted by

$$\mathfrak{g}, \mathfrak{n}, \mathfrak{a} \text{ and } \mathfrak{k}. \quad (192)$$

Here,

$$\begin{aligned} \mathfrak{g} &= \text{real matrices with zero trace} \\ \mathfrak{n} &= \text{subspace of strictly upper triangular matrices with zero diagonal} \\ \mathfrak{a} &= \text{subspace of diagonal matrices with zero trace} \\ \mathfrak{k} &= \text{subspace of skew-symmetric matrices.} \end{aligned} \quad (193)$$

The Iwasawa decomposition is unique, when

$$g = nak \quad (194)$$

we define the maps n, A, k by

$$g = n(g)A(g)k(g). \quad (195)$$

We also use the expression $\log A(g)$, where \log is the matrix logarithm. In the case of diagonal matrices,

$$a = \text{diag}(a_1, \dots, a_n) \quad (196)$$

with positive entries

$$\log a = \text{diag}(\log a_i), \quad (197)$$

hence,

$$A(g) = e^{\log A(g)}. \quad (198)$$

Remark 3. (i) The Lie algebra \mathfrak{a} is a $(n - 1)$ -dimensional real algebra, which, as a vector space, is equipped with a natural real, symmetric scalar product, namely, the trace form

$$\langle H_1, H_2 \rangle = \text{tr}(H_1 H_2), \quad H_i \in \mathfrak{a}. \quad (199)$$

(ii) Let \mathfrak{a}^* be the dual space of \mathfrak{a} . Its elements will be denoted by Greek symbols, some of which have special meanings in the literature. The linear forms are also called additive characters.

(iii) Let $\lambda \in \mathfrak{a}^*$, then there exists a unique matrix $H_\lambda \in \mathfrak{a}$, such that

$$\lambda(H) = \langle H_\lambda, H \rangle \quad \forall H \in \mathfrak{a}. \quad (200)$$

This definition allows defining a dual trace form in \mathfrak{a}^* by setting for $\lambda, \mu \in \mathfrak{a}^*$

$$\langle \lambda, \mu \rangle = \langle H_\lambda, H_\mu \rangle. \quad (201)$$

The Fourier theory in $X = G/K$, which we summarized in [3] (Section 6), uses the functions

$$e_{\lambda, b}(x) = e^{(i\lambda + \rho) \log A(x, b)}, \quad (\lambda, b) \in \mathfrak{a}^* \times B, \quad x \in X, \quad (202)$$

as the Fourier kernel, where

$$B = K/M. \quad (203)$$

Here, M is the centralizer of A in K and ρ is a special character with the norm

$$\langle \rho, \rho \rangle = \frac{1}{12}(n - 1)^2 n, \quad (204)$$

cf. [3] (Lemma 1). If $n = 3$, then

$$|\rho|^2 = 1. \quad (205)$$

For a precise definition of $A(x, b) \in A$, we refer to [3] (p. 19), which also contains references to the corresponding mathematical literature given, especially to Helgason's book [15] (Chapter III).

The Fourier transform for functions $f \in C_c^\infty(X, \mathbb{C})$ is then defined by

$$\hat{f}(\lambda, b) = \int_X f(x) e^{(-i\lambda + \rho) \log A(x, b)} dx \quad (206)$$

for $\lambda \in \mathfrak{a}^*$ and $b \in B$, or, if we use the definition in (202)

$$e_{\lambda, b}(x) = e^{(i\lambda + \rho) \log A(x, b)}, \quad (207)$$

by

$$\hat{f}(\lambda, b) = \int_X f(x) \bar{e}_{\lambda, b}(x) dx. \quad (208)$$

The functions $e_{\lambda, b}$ are real analytics in x and are eigenfunctions of the Laplacian, cf. [15] (Prop. 3.14, p. 99),

$$-\tilde{\Delta} e_{\lambda, b} = (|\lambda|^2 + |\rho|^2) e_{\lambda, b}, \quad (209)$$

where

$$|\lambda|^2 = \langle \lambda, \lambda \rangle, \quad (210)$$

cf. (201), and similarly for $|\rho|^2$. We also denote the Fourier transform by \mathcal{F} , such that

$$\mathcal{F}(f) = \hat{f}. \quad (211)$$

In Equation (209), we identified

$$\tilde{\Delta} = \Delta_M = \Delta_X. \quad (212)$$

In [3], we finally dropped the embellishment and simply wrote Δ when referring to the above Laplacian, but at the moment we refrain from doing so to avoid confusion.

We shall consider the eigenfunctions $e_{\lambda, b}$ as tempered distributions of the Schwartz space $\mathcal{S}(X)$ and shall use their Fourier transforms

$$\hat{e}_{\lambda, b} = \delta_{(\lambda, b)} = \delta_\lambda \otimes \delta_b \quad (213)$$

as the spatial eigenfunctions of

$$\mathcal{F}(-\Delta) = m(\mu) = (|\mu|^2 + |\rho|^2), \quad (214)$$

which is a multiplication operator, such that

$$\mathcal{F}(-\Delta) \hat{e}_{\lambda, b} = m(\mu) \hat{e}_{\lambda, b} = (|\lambda|^2 + |\rho|^2) \hat{e}_{\lambda, b}, \quad (215)$$

cf. [3] (Section 6) for details.

Looking at the Fourier transformed eigenfunctions

$$\hat{e}_{\lambda, b} = \delta_\lambda \otimes \delta_b \quad (216)$$

it is obvious that the dependence on b has to be eliminated, since there is neither a physical nor a mathematical motivation to distinguish between $e_{\lambda, b}$ and $e_{\lambda, b'}$. We discard the integration over B in [3] (Section 6) and pick instead a special element $b_0 \in B$, namely,

$$b_0 = eM, \quad e = \text{id} \in K, \quad (217)$$

and only consider the eigenfunctions e_{λ, b_0} with corresponding Fourier transforms

$$\delta_\lambda \equiv \delta_\lambda \otimes \delta_{b_0} = \hat{e}_{\lambda, b_0}, \quad \lambda \in \mathfrak{a}^*. \quad (218)$$

For justification, see [3] (Lemma 4) and the arguments preceding the referenced Lemma.

The eigenfunctions e_{λ, b_0} depend on the characters $\lambda \in \mathfrak{a}^*$ but not all characters are physically relevant. For a definition of the physically relevant characters, let us rephrase [3] (Remark 2, p. 18):

Remark 4. *There are characters α_{ij} , $1 \leq i < j \leq n$, that will represent the elementary gravitons stemming from the degrees of freedom in choosing the coordinates*

$$g_{ij}, \quad 1 \leq i < j \leq n, \quad (219)$$

of a metric tensor. The diagonal elements offer, in general, additional n degrees of freedom, but in our case, where we consider metrics satisfying

$$\det g_{ij} = 1, \quad (220)$$

only $(n - 1)$ diagonal components can be freely chosen, and we shall choose the first $(n - 1)$ entries, namely,

$$g_{ii}, \quad 1 \leq i \leq n - 1. \quad (221)$$

The corresponding additive characters are named α_i , $1 \leq i \leq n - 1$.

The characters α_i , $1 \leq i \leq n - 1$, and α_{ij} , $1 \leq i < j \leq n$ will represent the $\frac{(n+2)(n-1)}{2}$ elementary gravitons at the character level. We shall normalize the characters by defining

$$\tilde{\alpha}_i = \|H_{\alpha_i}\|^{-1} \alpha_i \quad (222)$$

and

$$\tilde{\alpha}_{ij} = \|H_{\alpha_{ij}}\|^{-1} \alpha_{ij} \quad (223)$$

such that the normalized characters have unit norm, cf. (201).

We can now define the corresponding forms in \mathfrak{a}^* with arbitrary energy levels:

Definition 1. *Let $\lambda \in \mathbb{R}_+$ be arbitrary. Then we consider the characters*

$$\lambda \tilde{\alpha}_i \quad \wedge \quad \lambda \tilde{\alpha}_{ij}, \quad (224)$$

where we recall that the terms embellished by a tilde refer to the corresponding unit vectors. Then the eigenfunctions representing the elementary gravitons are $e_{\lambda \tilde{\alpha}_i, b_0}$ and $e_{\lambda \tilde{\alpha}_{ij}, b_0}$.

The corresponding eigenvalue with respect to $-\tilde{\Delta}$ is $|\lambda|^2 + |\rho|^2$, where, by a slight abuse of notation, $|\lambda|^2 = \lambda^2$ and $|\rho|^2 = \langle \rho, \rho \rangle$. Note that $|\rho|^2 = 1$ if $n = 3$, cf. (205).

We define a zero-point energy eigenfunction by choosing $\lambda \in \mathfrak{a}^ = 0$. The corresponding eigenfunction would be e_{0, b_0} , satisfying*

$$-\tilde{\Delta} e_{0, b_0} = |\rho|^2 e_{0, b_0} = e_{0, b_0}. \quad (225)$$

if $n = 3$.

We are now able to quantize the Hamiltonian H in (181). For brevity we denote the quantized Hamiltonians, which are operators, by using the same symbols as for the Hamilton functions. For the Hamilton operator H_G , we express as in (183)

$$\begin{aligned} H_G u = & -\alpha_N \frac{n}{16(n-1)} t^{-m} \frac{\partial}{\partial t} (t^m \frac{\partial w}{\partial t}) v - \alpha_N t^{-2} w \tilde{\Delta} v \\ & - \alpha_N^{-1} t^{2-\frac{4}{n}} R(\sigma_{ij}) w v + 2\alpha_N^{-1} \Lambda t^2 w v, \end{aligned} \quad (226)$$

where we use the separation of variables in (186), the form of the metric in (125), namely,

$$g_{ij} = t^{\frac{4}{n}} \sigma_{ij} \quad (227)$$

and the relation between the scalar curvatures of conformal metrics

$$R(g) = t^{-\frac{4}{n}} R(\sigma). \quad (228)$$

Let us recall that for the quantization of \tilde{H}_{SM} we shall specify $\sigma_{ij} = \delta_{ij}$, such that the spatial eigendistributions, or approximate eigendistributions, ψ , satisfying

$$\tilde{H}_{SM}\psi = \lambda_1\psi, \quad \lambda_1 \geq 0 \quad (229)$$

can be derived by applying standard methods of QFT. We then solve the Wheeler–DeWitt equation

$$Hu = 0 \quad (230)$$

not for all $(t, \sigma_{ij}) \in \mathbb{R}^+ \times M$ but only for (t, δ_{ij}) , where $t > 0$ is arbitrary. Thus, we shall solve

$$-\tilde{\Delta}v = (|\lambda|^2 + |\rho|^2)v \quad (231)$$

by using

$$v = e_{\lambda, b_0} \quad (232)$$

for arbitrary $\sigma_{ij} \in M$, but we shall evaluate e_{λ, b_0} only at $\sigma_{ij} = \delta_{ij}$. Furthermore, we observe that for $x = gK \in X$ and $b = kM \in B$, we have

$$A(x, b) = A(gK, kM) = A(k^{-1}g), \quad (233)$$

cf. [3] (equ. (202), p. 18), hence, if $b = b_0$, i.e., if $k = e = \text{id}$, then

$$A(x, b_0) = A(g). \quad (234)$$

Moreover, let

$$\pi : G/K \rightarrow M \quad (235)$$

be the isometry, then

$$\pi(gK) = gg^*, \quad (236)$$

where g^* is the adjoint. Thus, if $g = (\delta_{ij}) = e$, we infer

$$\sigma_{ij} = \delta_{ij} \in M \implies e_{\lambda, b_0}(\sigma_{ij}) = 1, \quad (237)$$

and we have proved:

Theorem 3. Let $n = 3$, $v = e_{\lambda, b_0}$, and let ψ be an eigendistribution of \tilde{H}_{SM} when $\sigma_{ij} = \delta_{ij}$ such that

$$-\tilde{\Delta}e_{\lambda, b_0} = (|\lambda|^2 + 1)e_{\lambda, b_0}, \quad (238)$$

$$\tilde{H}_{SM}\psi = \lambda_1\psi, \quad \lambda_1 \geq 0, \quad (239)$$

and let w be a solution of the ODE

$$\begin{aligned} t^{-m} \frac{\partial}{\partial t} \left(t^m \frac{\partial w}{\partial t} \right) + \frac{32}{3} (|\lambda|^2 + 1) t^{-2} w + \frac{32}{3} \alpha_N^{-1} \lambda_1 t^{-\frac{2}{3}} w \\ + \frac{64}{3} \alpha_N^{-2} \Lambda t^2 w = 0 \end{aligned} \quad (240)$$

then

$$u = w e_{\lambda, b_0} \psi \quad (241)$$

is a solution of the Wheeler–DeWitt equation

$$Hu = 0, \quad (242)$$

where e_{λ, b_0} is evaluated at $\sigma_{ij} = \delta_{ij}$ and where we note that $m = 5$.

We shall refer to e_{λ, b_0} and ψ as the spatial eigenfunctions and to w as the temporal eigenfunction.

Remark 5. We could also apply the respective Fourier transforms to $-\tilde{\Delta}e_{\lambda, b_0}$ resp. $\tilde{H}_{SM}\psi$ and consider

$$w\hat{e}_{\lambda, b_0}\hat{\psi} \quad (243)$$

as the solution in the Fourier space, where $\hat{\psi}$ would be expressed with the help of the ladder operators.

In the next section, we shall analyze the temporal eigenfunctions.

5. Temporal Eigenfunctions

The temporal eigenfunctions have to satisfy the ODE (240) or equivalently

$$\begin{aligned} \ddot{w} + 5t^{-1}\dot{w} + \frac{32}{3}(|\lambda|^2 + 1)t^{-2}w + \frac{32}{3}\alpha_N^{-1}\lambda_1 t^{-\frac{2}{3}}w \\ + \frac{64}{3}\alpha_N^{-2}\Lambda t^2w = 0, \end{aligned} \quad (244)$$

where we used that $m = 5$, since we assume $n = 3$. Let us denote the other constants in front of the three lower order terms by m_1 , m_2^2 resp. m_3 , then the ODE appears as

$$\ddot{w} + 5t^{-1}\dot{w} + m_1 t^{-2}w + m_2^2 t^{-\frac{2}{3}}w + m_3 t^2w = 0, \quad (245)$$

where

$$m_1 \geq \frac{32}{3}, \quad m_2 \geq 0, \quad m_3 \in \mathbb{R}. \quad (246)$$

The ODE (245) has two linearly independent solutions that are smooth and defined for all $t > 0$. However, if m_2 , as well as m_3 are both different from zero, then the solution cannot be expressed by known functions, such as variants of the Bessel functions. Only if this is not valid, the solutions can be expressed by known functions.

Theorem 4. Assume $m_3 = 0$ and $m_2 > 0$, then the solutions of the ODE (245) are generated by

$$J\left(\frac{3}{2}\sqrt{m_1 - 4}i, \frac{3}{2}m_2 t^{\frac{2}{3}}\right)t^{-2} \quad (247)$$

and

$$J\left(-\frac{3}{2}\sqrt{m_1 - 4}i, \frac{3}{2}m_2 t^{\frac{2}{3}}\right)t^{-2}, \quad (248)$$

where $J(\lambda, t)$ is the Bessel function of the first kind.

Proof. We used Mathematica to obtain these solutions. The verification that these functions are indeed solutions is straightforward. \square

Lemma 4. The solutions in the theorem above diverge to complex infinity if t tends to zero and they converge to zero if t tends to infinity.

Proof. The results can be derived by looking at a series expansion of the corresponding Bessel functions near the origin resp. near infinity. \square

Next, let us consider the solutions when $m_2 = 0$ and $m_3 \neq 0$. Then we distinguish two cases $m_3 > 0$ resp. $m_3 < 0$. For a better distinction, we shall express m_3 in the form

$$m_3 = m_4^2, \quad m_4 > 0, \quad (249)$$

in the first case, and as

$$m_3 = -m_4^2, \quad m_4 > 0, \quad (250)$$

in the second case.

Theorem 5. Assume $m_2 = 0$ and $m_3 > 0$, then the solutions of the ODE (245) are generated by the functions

$$J\left(\frac{1}{2}\sqrt{m_1 - 4}i, \frac{1}{2}m_4t^2\right)t^{-2} \quad (251)$$

and

$$J\left(-\frac{1}{2}\sqrt{m_1 - 4}i, \frac{1}{2}m_4t^2\right)t^{-2}, \quad (252)$$

where $J(\lambda, t)$ is the Bessel function of the first kind.

Similarly, we obtain in the second case:

Theorem 6. Assume $m_2 = 0$ and $m_3 < 0$, then the solutions of the ODE (245) are generated by the functions

$$I\left(\frac{1}{2}\sqrt{m_1 - 4}i, \frac{1}{2}m_4t^2\right)t^{-2} \quad (253)$$

and

$$I\left(-\frac{1}{2}\sqrt{m_1 - 4}i, \frac{1}{2}m_4t^2\right)t^{-2}, \quad (254)$$

where $I(\lambda, t)$ is the modified Bessel function of the first kind. In Mathematica, this function is denoted by `BesselI`[λ, t].

The arguments in the proof of Theorem 4 also apply in the case of Theorems 5 and 6.

Lemma 5. The solutions in Theorem 5 resp. Theorem 6 diverge to complex infinity if t tends to zero, as well as if t tends to infinity.

Proof. The same arguments as in the proof of Lemma 4 apply. \square

6. Conclusions

The temporal eigenfunctions in the theorems of the previous section all become unbounded if $t \rightarrow 0$, which can be described as a big bang on a quantum level. Furthermore, if we consider $t < 0$, then the functions

$$\tilde{w}(t) = w(-t), \quad t < 0, \quad (255)$$

also satisfy the ODE (244) for $t < 0$, if we replace $t^{-\frac{2}{3}}$ by $|t|^{-\frac{2}{3}}$, i.e., they are also temporal eigenfunctions if the light cone in E is flipped.

Thus, we conclude

Theorem 7. The quantum model we derived for gravity combined with the forces of the standard model can be described by products of spatial and temporal eigenfunctions of corresponding self-adjoint operators with a continuous spectrum.

We have a zero-point energy state as a spatial eigendistribution of the gravitational Hamiltonian with the smallest eigenvalue $|\rho|^2 = 1$, which could be considered the source of the dark energy.

Furthermore, we have a big bang singularity in $t = 0$. Since the same quantum model is also valid by switching from $t > 0$ to $t < 0$, with appropriate changes to the temporal eigenfunctions, one could argue that at the big bang, two universes with different time orientations could have

been created, such that, in view of the CPT theorem, one was filled with matter and the other with anti-matter.

Remark 6. One of the reviewers raised two questions. First, he wondered about the logic to combine a low energy event, the quantization of the fields of the standard model with a flat metric, with an high-energy event, the quantization of gravity. As we have already pointed out in the introduction, a unified quantization of gravity and matter fields leads to a hyperbolic equation of second order in a fiber space, where the main part of the hyperbolic operator acts in the fibers. The zero-order terms of the operator contain the contributions of the quantized matter Hamiltonian and the interaction of gravity with matter fields occurs with the help of the fiber variables (t, σ_{ij}) . The metric σ_{ij} is used in the quantization of the matter fields. Looking at the spatial eigenfunction v of the gravitational Hamiltonian and its eigenvalue, which expresses the energy, then the eigenvalue is independent of the metric σ_{ij} at which v is evaluated and only the evaluation point is relevant for the interaction, i.e., even if a non-flat metric σ_{ij} would have been used in the quantization of the matter fields, the contribution to the unified operator would not have changed qualitatively. Furthermore, as we already mentioned in the introduction, due to the scalar curvature term R , we cannot expect to solve the Wheeler–DeWitt equation for all (t, σ_{ij}) if we use the separation of variables, instead, we have to choose metrics with constant scalar curvatures. Thus, we opted for $\sigma_{ij} = \delta_{ij}$, also out of necessity because we could not quantize the matter field in the curved spacetime.

The second interaction with respect to the variable t , the quantum time, is realized in the ODE, where the contributions by the spatial gravitational resp. matter eigenfunctions and also by the cosmological constant Λ have a power of t as a multiplicative factor with different exponents. For small t , the gravitational energy dominates because of the factor t^{-2} , for larger t , the matter energy dominates because of the factor $t^{-\frac{2}{3}}$, and if $\Lambda \neq 0$, then the cosmological constant dominates for very large t because of the factor t^2 . This is also reflected in the results of Lemmas 4 and 5.

The second question raised concerned the QFT renormalizability in this unified setting.

The quantization of gravity takes place in the fibers of E while the quantization of the matter fields takes place in the base space $S_0 = \mathbb{R}^n$, which we equipped with the Euclidean metric for this task. Hence, the usual renormalization techniques can be used to deal with infinities. The fibers are ignored in this process.

Remark 7. The Academic Editor of the journal also requested some observational predictions of the theory presented in this paper.

In Theorem 7, we already offered possible answers to two open questions, namely, the source of the dark energy and why matter dominates anti-matter.

The Big Bang is only predicted by the singularity of the Friedmann model, a classical theory. In this paper, the Big Bang is predicted on a quantum level, which is a more appropriate level because the Big Bang is certainly a quantum event.

Powerful gravitational waves might be caused by quantum gravitational forces, such as the collision of two black holes. If this is the case, then they should satisfy an ODE similar to what we analyzed in Section 5. The patterns produced by the wave detectors should be similar to the plots produced by the solutions of the ODE in (244) on page 23, though the scalar curvature term does not appear in the ODE since $R(\delta_{ij}) = 0$, and in the case of black holes, R would be constant but different from zero, i.e., the ODE should contain a term, probably positive, with the factor $t^{\frac{2}{3}}$, and most likely no contribution by the standard model fields.
