#### Abstract

Geometries, equilibrium dissociation energies ( $D_{\mathrm{e}}$ ), intermolecular stretching, and quadratic force constants ( $k_{\sigma}$ ) determined by ab initio calculations conducted at the CCSD $(T) /$ aug-cc-pVTZ level of theory, with $D_{\mathrm{e}}$ obtained by using the complete basis set (CBS) extrapolation [CCSD(T)/CBS energy], are presented for the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes, where B is one of the following Lewis bases: $\mathrm{CO}, \mathrm{H}_{2} \mathrm{~S}, \mathrm{PH}_{3}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{NH}_{3}$, and R is $\mathrm{H}, \mathrm{F}$ or $\mathrm{CH}_{3}$. The $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ precursor molecules were shown to be linear and non-dipolar. The non-covalent intermolecular bond in the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ complexes is shown to result from the interaction of the electrophilic band around the Be atom of $\mathrm{BeR}_{2}$ (as indicated by the molecular electrostatic potential surface) with non-bonding electron pairs of the base, B , and may be described as a beryllium bond by analogy with complexes such as $\mathrm{B} \cdots \mathrm{CO}_{2}$, which contain a tetrel bond. The conclusions for the $\mathrm{B} \cdots \mathrm{MgR}_{2}$ series are similar and a magnesium bond can be correspondingly invoked. The geometries established for $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ can be rationalized by a simple rule previously enunciated for tetrel-bonded complexes of the type $\mathrm{B} \cdots \mathrm{CO}_{2}$. It is also shown that the dissociation energy, $D_{\mathrm{e}}$, is directly proportional to the force constant, $k_{\sigma}$, in each $\mathrm{B} \cdots \mathrm{MR}_{2}$ series, but with a constant of proportionality different from that established for many hydrogen-bonded B $\cdots$ HX complexes and halogen-bonded B $\cdots$ XY complexes. The values of the electrophilicity, $E_{\mathrm{A}}$, determined from the $D_{\mathrm{e}}$ for $\mathrm{B} \cdots \mathrm{BeR}_{2}$ complexes for the individual Lewis acids, A , reveal the order $\mathrm{A}=\mathrm{BeF}_{2}>\mathrm{BeH}_{2}>\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$-a result that is consistent with the -I and +I effects of F and $\mathrm{CH}_{3}$ relative to H . The conclusions for the $\mathrm{MgR}_{2}$ series are similar but, for a given R, they have smaller electrophilicities than those of the $\mathrm{BeR}_{2}$ series. A definition of alkaline-earth non-covalent bonds is presented.

Keywords: magnesium bonds; beryllium bonds; ab initio calculations; binding strength; electrophilicity and nucleophilicity

## 1. Introduction

The non-covalent interactions of closed-shell molecules represent an important subject in many areas of chemistry and biology. The central position of the hydrogen bond in these disciplines is well known. Since the 1950s, there has been a rapid growth of interest in other non-covalent interactions. The halogen bond was first named and identified experimentally in the solid state in the 1950s by Hassel [1], and then in the gas phase as a weak interaction involving simple Lewis bases with di-halogen molecules in the 1990s [2]. The halogen bond was shown [2,3] to have properties similar to those of the hydrogen bond. Interest in the halogen bond has grown rapidly within chemistry, biology
and materials science in the last two decades [4,5]. The comprehensive definitions of the hydrogen bond and the halogen bond by working parties set up by IUPAC were published in 2011 [6] and 2013 [7], respectively. The definition of the halogen bond explicitly invokes the interaction of a halogen atom (acting as an electrophile) with a non-bonding or $\pi$-bonding electron pair (the nucleophilic region) of, for example, a Lewis base. Tetrel bonds, pnictogen bonds, and chalcogen bonds are non-covalent interactions that have been investigated extensively in the gas phase [8] and condensed phase [9] since the 1970s, but were only named according to the group in the periodic table from which the atom acting as the electrophile originates (Groups 14, 15 and 16, respectively) in 2013 [10], 2011 [11], and 2009 [12], respectively. The IUPAC definitions of these newer types of interactions, similar to that of the halogen bond, are imminent [13]. However, the general applicability of such definitions based on electrostatics alone has been questioned in the case of some of the more unusual types of non-covalent interactions [14-17]. Other non-covalent interactions involving atoms of other groups in the periodic table acting as the electrophilic region can be identified. A recent example is the so-called coinage-metal bond $B \cdots M X$, where $B$ is a Lewis base and $M$ is a Group 11 metal atom [18].

In this article, we report an investigation, by means of high-level ab initio calculations, of $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes in which B is one of the six simple Lewis bases $\mathrm{CO}, \mathrm{H}_{2} \mathrm{~S}, \mathrm{PH}_{3}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{NH}_{3}$ and R is $\mathrm{H}, \mathrm{F}$ or $\mathrm{CH}_{3}$. We will show that various Lewis acid molecules, $\mathrm{BeR}_{2}$ and MgR 2 , are linear, non-dipolar, and of geometry $\mathrm{R}-\mathrm{Be}-\mathrm{R}$ and $\mathrm{R}-\mathrm{Mg}-\mathrm{R}$. In each case, we also show, from the molecular electrostatic surface potentials, that there is a positive belt around the central Group 2 atom which can act as the electrophilic region when forming either a beryllium or a magnesium bond [19] to the most nucleophilic region (a non-bonding electron pair) of the Lewis base. As well as the geometry optimizations of the complexes, we also calculate two measures of the binding strength, namely, the equilibrium dissociation energy, $D_{\mathrm{e}}$, and the intermolecular stretching force constant, traditionally referred to as $k_{\sigma}$ [2]. The first is the energy required to remove the component molecules from the hypothetical equilibrium separation to infinite distance, while the second is a measure of the work required for a unit infinitesimal displacement from the equilibrium. It has been shown [20-22] that for a wide range of hydrogen-, halogen-, tetrel-, pnictogen- and chalcogen-bonded complexes, $D_{\mathrm{e}}$ is directly proportional to $k_{\sigma}$ and, moreover, that it is possible to reproduce the $D_{\mathrm{e}}$ values (and, therefore, the $k_{\sigma}$ values also) by assigning a set of electrophilicities, $E_{\mathrm{A}}$, to the Lewis acids, A , and nucleophilicities, $N_{\mathrm{B}}$, to the Lewis bases, B. An important aim of the present article is to discover whether this partitioning also applies to beryllium- and magnesium-bonded complexes.

Another aim of this study is to examine the effects of replacing both H atoms in $\mathrm{H}-\mathrm{Be}-\mathrm{H}$ and $\mathrm{H}-\mathrm{Mg}-\mathrm{H}$, firstly by F and secondly by $\mathrm{CH}_{3}$ groups. According to the electronic theory of organic chemistry developed by Ingold [23] and in particular the inductive effect I, F removes electronic charge from the central atom relative to the hydride (the $-I$ effect), while the methyl group pushes electrons towards the central atom through the $+I$ effect. If so, the central Group 2 atom should become more electrophilic ( $E_{\mathrm{A}}$ should increase relative to that of the dihydride) in $\mathrm{F}-\mathrm{Be}-\mathrm{F}$ and $\mathrm{F}-\mathrm{Mg}-\mathrm{F}$, but less electrophilic (decease of $E_{\mathrm{A}}$ ) in $\mathrm{CH}_{3}-\mathrm{Be}-\mathrm{CH}_{3}$ and $\mathrm{CH}_{3}-\mathrm{Mg}-\mathrm{CH}_{3}$. This conclusion is confirmed by the molecular electrostatic potential surfaces (MEPS) of $\mathrm{F}-\mathrm{Be}-\mathrm{F}$, $\mathrm{H}-\mathrm{Be}-\mathrm{H}$ and $\mathrm{CH}_{3}-\mathrm{Be}-\mathrm{CH}_{3}$. These were calculated for the $0.001 \mathrm{e} / \mathrm{bohr}^{3}$ electron density isosurface at the CCSD/aug-cc-pVTZ/ /CCSD(T)/aug-cc-pVTZ level of theory with the Gaussian-16 Program [24] and are shown in Figure 1. In each case, there is a blue belt that surrounds the central Be atoms. The deepest blue color corresponds to the most positive MEPS in each case and has a maximum value of 337,167 and $119 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ for $\mathrm{F}-\mathrm{Be}-\mathrm{F}, \mathrm{H}-\mathrm{Be}-\mathrm{H}$ and $\mathrm{CH}_{3}-\mathrm{Be}-\mathrm{CH}_{3}$, respectively. Thus, the blue belt surrounding the Be atom is the most electrophilic region in each molecule and the electrophilicity is greatest when F is the ligand and smallest when $\mathrm{CH}_{3}$ is the ligand, in agreement with the -I and +I inductive effects of F and $\mathrm{CH}_{3}$, respectively. Similar patterns are observed from the MEPSs of the Mg analogues (see Supplementary Material, Figure S1), except that for a given ligand, R, the maximum positive potential is higher for Mg than for Be , with values of 753,321 and $280 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, for $\mathrm{R}=\mathrm{F}$, H and $\mathrm{CH}_{3}$, respectively.

Figure 1. Molecular electrostatic potential surfaces of the linear non-polar molecules, $\mathrm{BeF}_{2}, \mathrm{BeH}_{2}$ and $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$ calculated at the $0.001 \mathrm{e} /$ bohr $^{3}$ electron density isosurface at the CCSD/ aug-cc-pVTZ// $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of theory. The surface has been is made transparent to reveal the molecular model within. The most intense blue (and, therefore, the most electrophilic) belts centered on Be correspond to positive electrostatic potential energies of 337,167 and $119 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ for $\mathrm{BeF}_{2}$, $\mathrm{BeH}_{2}$ and $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$, respectively, and confirm expectations based on the inductive effects of $\mathrm{CH}_{3}$ and F relative to H .

## 2. Results

### 2.1. Molecular Geometries

The molecular diagrams (drawn to scale) of the geometries of the three Lewis acids $\mathrm{BeF}_{2}$, $\mathrm{BeH}_{2}$ and $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$ optimized at the $\mathrm{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of theory are shown in Figure 2. The geometries belong to the point groups $D_{\infty h}, D_{\infty h}$ and $D_{3 d}$, respectively, and are consistent with two singly occupied sp hybrid orbitals on the central Be atom forming bonds with F, H or C, respectively. The similarly determined geometries for the three Mg analogues are isostructural with their Be counterparts, but are not shown. They are available from the Supplementary Material, which includes the optimized cartesian coordinates of atoms for all molecules investigated here.

Figure 2. Geometries of $\mathrm{BeF}_{2}, \mathrm{BeH}_{2}$ and $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$ optimized at the $\mathrm{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of theory (to scale).

Figure 3 displays the molecular diagrams (drawn to scale) of the six $\mathrm{B} \cdots \mathrm{BeF}_{2}$ complexes in which B $=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{PH}_{3}$. The molecular diagrams of the corresponding sets of six $\mathrm{B} \cdots \mathrm{BeH}_{2}$ and $\mathrm{B} \cdots \mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$ complexes are shown in Figures 4 and 5 , respectively. In each case, the fragment $\mathrm{R}_{2} \mathrm{Be} \cdots \mathrm{L}$, where L is the atom of B involved in the intermolecular bond, is Y -shaped (local symmetry $C_{2 v}$ ). Thus, the angle, $\theta$ (which is defined in Figure 3), is zero in the $B e R_{2}$ monomer molecules, but increases significantly in all $\mathrm{B} \cdots \mathrm{BeR}_{2}$ complexes investigated, as indicated by the values included in Table 1. The Y shape can be explained if it is assumed that, when the Lewis base, B, approaches $R-B e-R$ and forms the complex, the hybridization at the central Be atom starts to change to $\mathrm{sp}^{2}$ and the third (empty) $\mathrm{sp}^{2}$ orbital receives the non-bonding electron pair of $B$ with the result that a partial dative bond $\mathrm{Be}-\mathrm{L}$ is formed with the acceptor atom of B . It is clear from Table 1 that the angles $\mathrm{R}-\mathrm{Be}-\mathrm{R}$ are all less than $180^{\circ}$ in the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ complexes but are greater than the ideal $\mathrm{sp}^{2}$ angles of $120^{\circ}$ that would occur for a fully dative bond (i.e., $0^{\circ}<\theta<30^{\circ}$ ). The $\mathrm{BeCl}_{3}{ }^{-}$anion [25] has three equivalent $\mathrm{Be}-\mathrm{Cl}$ bonds and $D_{3 \mathrm{~h}}$ symmetry, with ideal $120^{\circ}$ angles. There are also increases $\delta r$ in the distances $r(\mathrm{R}-\mathrm{Be})$ on formation of all $\mathrm{B} \cdots \mathrm{BeR}_{2}$ complexes considered here, as expected for the partial change from sp to $\mathrm{sp}^{2}$ hybridization at Be . The values of $\delta r$ for all $\mathrm{B} \cdots \mathrm{BeR}_{2}$ complexes investigated are included in Table 1.

Figure 3. Geometries (drawn to scale) of six $\mathrm{B} \cdots \mathrm{BeF}_{2}$ complexes optimized at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of theory, where $\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{PH}_{3}$.

Figure 4. Geometries (drawn to scale) of six $\mathrm{B} \cdots \mathrm{BeH}_{2}$ complexes optimized at the $\mathrm{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of theory, where $\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{PH}_{3}$.

Figure 5. Geometries (drawn to scale) of six $\mathrm{B} \cdots \mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$ complexes optimized at the $\mathrm{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of theory, where $\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{PH}_{3}$.

The observations about the angle $\theta$ and the increase $\delta r$ in the distances $r(\mathrm{R}-\mathrm{Mg})$ also apply to the formation of the $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes from the various $\mathrm{MgR}_{2}$ molecules. Table 2 includes these quantities for the 18 complexes that result from the interaction of the three $\mathrm{MgR}_{2}$ molecules $(\mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3}$ ) with the set of six Lewis bases, $\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{PH}_{3}$. The full geometries of these complexes are available in the form of the cartesian coordinates in the Supplementary Material. We note from Tables 1 and 2 that the distance $r(\mathrm{Mg} \cdots \mathrm{L})$ is correlated with the strength of the interaction in the Mg series, in the sense that shorter distances are associated with larger $D_{\mathrm{e}}$ values; the correlation is less clear in the Be series.

### 2.2. Relationship between $D_{e}$ and $k_{\sigma}$

The two measures ( $D_{\mathrm{e}}$ and $k_{\sigma}$ ) of the binding strength obtained through ab initio calculations for the $18 \mathrm{~B} \cdots \mathrm{BeR}_{2}$ complexes discussed in Section 2.1 are given in Table 1. The corresponding quantities for the $18 \mathrm{~B} \cdots \mathrm{MgR}_{2}$ are in Table 2. It should be noted, from Tables 1 and 2, that these complexes
tend to be more strongly bound according to both criteria ( $D_{\mathrm{e}}$ and $k_{\sigma}$ ) than those of a wide range of hydrogen-, halogen-, tetrel-, pnictogen- and chalcogen-bonded complexes with a similar set of Lewis bases previously investigated [20-22]. Typically, for the hydrogen- and halogen-bonded complexes considered in [22], for example, $D_{\mathrm{e}} \approx 20 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ and $k_{\sigma} \approx 10 \mathrm{~N} \cdot \mathrm{~m}^{-1}$. This larger binding strength of the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes is reflected in the significant geometrical distortions in $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ on complex formation noted in Section 2.1. Given the direct proportionality of $D_{\mathrm{e}}$ and $k_{\sigma}$ established in refs. [20-22] for hydrogen- and halogen-bonded complexes, it is of interest to examine whether a similar relationship between the two quantities holds for the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes discussed here.

Figure 6 shows a plot of $D_{\mathrm{e}}$ versus $k_{\sigma}$ for the $18 \mathrm{~B} \cdots \mathrm{BeR}_{2}$ complexes $\left(\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}\right.$, $\mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{PH}_{3} ; \mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\left.\mathrm{CH}_{3}\right)$. The result of a linear regression fit to the points is also shown. The points lie on a reasonably good straight line, which passes through the origin. Two minima at the $\operatorname{CCSD}(\mathrm{T})$ /aug-cc-pVTZ level were found for $\mathrm{OC} \cdots \mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$. The first minimum occurs at a Be $\cdots \mathrm{C}$ distance of $2.19 \AA$ with $D_{\mathrm{e}}=3.66 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, while the second (and global) minimum is at $2.92 \AA$ with $D_{\mathrm{e}}$ of $5.28 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$. The barrier between the two minima is less than $0.01 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$. Figure 7 is the plot of $D_{\mathrm{e}}$ versus $k_{\sigma}$ for the $18 \mathrm{~B} \cdots \mathrm{MgR}_{2}$ complexes. Thus, as found for a wide range of hydrogen-bonded $\mathrm{B} \cdots \mathrm{HX}$ complexes, halogen-bonded $\mathrm{B} \cdots \mathrm{XY}$ complexes and tetrel-, pnictogen- and chalcogen-bonded complexes [20,21], $D_{\mathrm{e}}$ is, in good approximation, directly proportional to $k_{\sigma}$ for both $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ series; that is, $D_{\mathrm{e}}=c^{\prime} \cdot k_{\sigma}$, where $c^{\prime}$ is the constant of proportionality.

Figure 6. Variation of ab initio-calculated values of $D_{e}$ with $k_{\sigma}$ for $18 \mathrm{~B} \cdots \mathrm{BeR}_{2}$ complexes ( $\mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3} ; \mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ or $\left.\mathrm{PH}_{3}\right)$. For the linear regression, $R^{2}=0.939$.

Figure 7. Variation of ab initio calculated values of $D_{e}$ with $k_{\sigma}$ for $18 \mathrm{~B} \cdots \mathrm{MgR}_{2}$ complexes $(\mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3} ; \mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ or $\left.\mathrm{PH}_{3}\right)$. For the linear regression, $R^{2}=0.952$.

Although a single value of $c^{\prime}=1.40(4) \times 10^{3} \mathrm{~m}^{2} \cdot \mathrm{~mol}^{-1}$ was obtained by fitting all five types of complexes (hydrogen-, halogen-, tetrel-, pnictogen- and chalcogen-bonded) discussed in [20], the values of $c^{\prime}$ obtained from the linear regressions in Figures 6 and 7 for $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ are significantly smaller at $0.79(5) \times 10^{3} \mathrm{~m}^{2} \cdot \mathrm{~mol}^{-1}$ and $1.07(6) \times 10^{3} \mathrm{~m}^{2} \cdot \mathrm{~mol}^{-1}$, respectively. It should be noted, however, that the beryllium and magnesium bonds considered here are much stronger for a given $B$ and the molecular distortions on formation of these bonds are greater than those for the other five types of non-covalent interactions listed. Plots of $D_{e}$ versus $k_{\sigma}$ for $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes for a given Lewis base, B , with a variation of the six Lewis acids ( $\mathrm{R}=\mathrm{H}, \mathrm{F}$ and $\mathrm{CH}_{3}$ ) show much weaker correlation and are less informative. Oliveira, Kraka and Cremer [14,26] have published plots which show the variation of relative bond strength order versus local stretching force constant as a gentle, smooth curve for many halogen- and chalcogen-bonded complexes.

### 2.3. Nucleophilicities of $B$ and Electrophilicities of $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}\left(\mathrm{R}=\mathrm{F}, \mathrm{H}\right.$ or $\left.\mathrm{CH}_{3}\right)$

It has been shown that for complexes involving hydrogen bonds, halogen bonds, tetrel bonds, pnictogen bonds and chalcogen bonds, $D_{\mathrm{e}}$ can be represented by an equation of the type

$$
\begin{equation*}
D_{\mathrm{e}}=c N_{\mathrm{B}} E_{\mathrm{A}}+d \tag{1}
\end{equation*}
$$

where $N_{\mathrm{B}}$ is the nucleophilicity of the Lewis base, $\mathrm{B}, E_{\mathrm{A}}$ is the electrophilicity of the Lewis acid, A , and $c$ and $d$ are constants. It is convenient to define $c=1.00 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ so that $N_{\mathrm{B}}$ and $E_{\mathrm{A}}$ are dimensionless. Given the direct proportionality of $D_{\mathrm{e}}$ and $k_{\sigma}$, Equation (1) can be recast with $k_{\sigma}$ as the subject and indeed it was with that version of the expression that $N_{\mathrm{B}}$ and $E_{\mathrm{A}}$ were first proposed for hydrogen-bonded complexes [27]. Here, we will use the version defined as Equation (1). It has also been established that the constant term, $d$, is usually small and can be negligible. Whether or not that is the case, the plots of $D_{\mathrm{e}}$ versus $N_{\mathrm{B}}$ are usually good straight lines and it follows then that the gradient is $\mathrm{d} D_{\mathrm{e}} / \mathrm{d} N_{\mathrm{B}}=c E_{\mathrm{A}}$. In the earlier determinations of $N_{\mathrm{B}}$ and $E_{\mathrm{A}}$ for the $\mathrm{B} \cdots \mathrm{HX}$ complexes $(\mathrm{X}=$ $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, etc.), the following procedure was used. The values of $N_{\mathrm{B}}$ were assigned to the various Lewis bases so that the plot of $D_{\mathrm{e}}$ (or $k_{\sigma}$ ) versus $N_{\mathrm{B}}$ for the $\mathrm{B} \cdots \mathrm{HF}$ complexes is a straight line through the origin. The sets of $D_{\mathrm{e}}$ for the $\mathrm{B} \cdots \mathrm{HCl}, \mathrm{B} \cdots \mathrm{HBr}$, etc., complexes were then plotted against $N_{\mathrm{B}}$ values so defined to give good straight lines, the gradients of which then defined the electrophilicities of the various HX molecules. An alternative procedure, used in [20], is to assign $N_{\mathrm{B}}$ and $E_{\mathrm{A}}$ values by a global fit of the $D_{\mathrm{e}}$ values of 250 complexes held together by a wide range of non-covalent bonds. The graphical approach, however, is useful for illustrating systematic relationships between different series of complexes and is employed here for the six $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ series ( $\mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3}$ ).

Figure 8 shows the plots of $D_{\mathrm{e}}$ versus $N_{\mathrm{B}}$ for the series of $\mathrm{B} \cdots \mathrm{MgF}_{2}, \mathrm{~B} \cdots \mathrm{MgH}_{2}$ and $\mathrm{B} \cdots \mathrm{Mg}\left(\mathrm{CH}_{3}\right)_{2}$ complexes when $\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{PH}_{3}$. The values of $\mathrm{N}_{\mathrm{B}}$ are those appropriate to the B $\cdots \mathrm{HF}$ series when $N_{\mathrm{NH} 3}$ is set to 7.5 to be consistent with its value reported in [20]. The remainder of $N_{\mathrm{B}}$ are those chosen so that the points in a plot of $D_{\mathrm{e}}$ versus $N_{\mathrm{B}}$ for all the B $\cdots$ HF complexes (data from [20]) lie on a straight line through the origin and are given in Table 3. This line for the $\mathrm{B} \cdots \mathrm{HF}$ is included in Figure 8 together with plots of $D_{\mathrm{e}}$ versus $N_{\mathrm{B}}$ for $\mathrm{B} \cdots \mathrm{HCl}$ and $\mathrm{B} \cdots \mathrm{HBr}\left(D_{\mathrm{e}}\right.$ values from [20]) against the set of $N_{B}$ defined by B $\cdots$ HF. The straight lines for the $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes are from least squares fits of the points (but with the points for $\mathrm{B}=\mathrm{H}_{2} \mathrm{O}$ excluded for reasons given below) for each series and the gradients of the fits $\mathrm{d} D_{\mathrm{e}} / \mathrm{d} N_{\mathrm{B}}=\mathrm{c} E_{\mathrm{A}}$ lead to the $E_{\mathrm{A}}$ values for $\mathrm{A}=\mathrm{MgF}_{2}$, $\mathrm{MgH}_{2}, \mathrm{Mg}\left(\mathrm{CH}_{3}\right)_{2}, \mathrm{HF}, \mathrm{HBr}$ and HCl listed in Table 3. The corresponding diagram for the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ series is in Figure 10, in which the plots for $\mathrm{B} \cdots \mathrm{HX}(\mathrm{X}=\mathrm{F}, \mathrm{Cl}$ and Br$)$ are included. The points for $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{BeR}_{2}$ were again excluded from the linear regression fits. The values of $E_{\mathrm{A}}$ derived from the gradients are in Table 3. The $N_{\mathrm{B}}$ and $E_{\mathrm{A}}$ values determined from the global fit of the $D_{\mathrm{e}}$ values of 250 hydrogen-, halogen-, tetrel-, pnictogen- and chalcogen-bonded complexes [20] are included in Table 3 for comparison. It is clear that there is reasonably good agreement between the $N_{B}$ values obtained here and those in ref. [20]. The same good agreement holds for the $E_{\mathrm{A}}$ values of HCl and HBr .

The reason for excluding the $D_{e}$ values of the $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{MgR}_{2}$ and $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{BeR}_{2}$ complexes from Figures 8 and 10, respectively, is that they imply $N_{\mathrm{H} 2 \mathrm{O}}$ values which significantly exceed those obtained from the $\mathrm{B} \cdots \mathrm{HF}$ data here (5.24) or from the global fit (4.89) in ref. [20] for $\mathrm{H}_{2} \mathrm{O}$. If the value of $D_{\mathrm{e}}$ for each $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{MgR}_{2}$ were forced to lie on its appropriate regression line in Figure 8, the value $N_{\mathrm{H} 2 \mathrm{O}} \approx 6.4$ would be necessary for each $R$. A similar conclusion applies for the $B \cdots B R_{2}$ complexes, implying that $N_{\mathrm{H} 2 \mathrm{O}} \approx 6.1$. Thus, $\mathrm{H}_{2} \mathrm{O}$ has a higher electrophilicity for the $\mathrm{MR}_{2}$ molecules than it does for HF. This could be related to the efficacy of water as a solvent for ions.

Figure 8. $D_{e}$ versus the nucleophilicity, $N_{B}$, for the $\mathrm{B} \cdots \mathrm{MgR}_{2}$ series and $\mathrm{B} \cdots \mathrm{HX}$ complexes ( $\mathrm{B}=\mathrm{CO}$, $\mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{PH}_{3} ; \mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3} ; \mathrm{X}=\mathrm{F}, \mathrm{Cl}$ or Br$)$. The $N_{\mathrm{B}}$ values are defined by the $B \cdots$ HF straight line through the origin (see text for details). The points for $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{MgR}_{2}$ were excluded from the regression fits for reasons discussed in the text. The lines and points for $\mathrm{B} \cdots \mathrm{HCl}$ and $\mathrm{B} \cdots \mathrm{HBr}$ are almost coincident. $\left(R^{2}=0.994,0.994,0.990,1.000,0.993\right.$ and 0.988 for the $\mathrm{Mg}\left(\mathrm{CH}_{3}\right)_{2}, \mathrm{MgH}_{2}, \mathrm{MgF}_{2}$, $\mathrm{HF}, \mathrm{HCl}$ and HBr lines, respectively).

Figure 9. The relationship between the conceptual DFT electrophilicity index, $\omega$, calculated from Equation (2) at the CCSD/aug-cc-pVTZ//CCSD(T)/aug-cc-pVTZ level of theory, and the $E_{\mathrm{A}}$ determined here for various $\mathrm{MR}_{2}$ molecules $\left(\mathrm{M}=\mathrm{Be}\right.$ or $\mathrm{Mg}, \mathrm{R}=\mathrm{F}, \mathrm{H}$, or $\mathrm{CH}_{3}$ ).

Table 3. Nucleophilicities of six Lewis bases, B, and electrophilicities of nine Lewis acids, A.

| Nucleophilicities |  |  | Electrophilicities |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Lewis Base B | $\boldsymbol{N}_{\mathbf{B}}$ (This Work) $^{\mathbf{a}}$ | $\boldsymbol{N}_{\mathbf{B}}$ (From [20]) $^{\mathbf{b}}$ | Lewis Acid A $^{\prime} \boldsymbol{E}_{\mathbf{A}}$ (This Work) $^{\mathbf{c}}$ | $\boldsymbol{E}_{\mathbf{A}}$ (From [20]) $^{\mathbf{b}}$ |  |
| CO | 2.14 | 2.12 | $\mathrm{BeF}_{2}$ | $17.5(4)$ | - |
| $\mathrm{PH}_{3}$ | 2.86 | 3.12 | $\mathrm{BeH}_{2}$ | $14.9(6)$ | - |

|  |  |  | HCl | $4.7(2)$ | 4.36 |

${ }^{\text {a }}$ Calculated by assuming that $D_{\mathrm{e}}=c N_{\mathrm{B}} E_{\mathrm{A}}$ with $\mathrm{c}=1.00 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ and $N_{\mathrm{NH} 3}=7.50$ and that all $D_{\mathrm{e}}$ for the $\mathrm{B} \cdots \mathrm{HF}$ complexes (from ref. [21]) lie on a straight line through the origin. ${ }^{\mathrm{b}}$ Values from ref. [20] when determined by a global fit to $D_{\mathrm{e}}$ values of 250 complexes held together by various types of non-covalent bonds. ${ }^{\text {c }}$ Obtained from the gradient $\mathrm{d} D_{\mathrm{e}} / \mathrm{d} N_{\mathrm{B}}=\mathrm{c} E_{\mathrm{A}}$ of the linear regression fit of each set of points in Figures 9 and 10.

Figure 10. $D_{e}$ versus the nucleophilicity, $N_{B}$, for the series $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{HX}$ complexes $(\mathrm{B}=\mathrm{CO}$, $\mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{PH}_{3} ; \mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3} ; \mathrm{X}=\mathrm{F}, \mathrm{Cl}$ or Br$)$. The $N_{\mathrm{B}}$ values are defined by the B $\cdots$ HF straight line through the origin (see text for details). The points for $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{BeR}_{2}$ were excluded from the regression fits for reasons discussed in the text. The regression lines and points for $\mathrm{B} \cdots \mathrm{HCl}$ and $\mathrm{B} \cdots \mathrm{HBr}$ are almost coincident. To avoid congestion, the regression line for the $\mathrm{B} \cdots \mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$ points has been omitted. ( $R^{2}=0.994,0.996,0.998,1.000 .0 .993$ and 0.988 for $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}, \mathrm{BeH}_{2}, \mathrm{BeF}_{2}, \mathrm{HF}, \mathrm{HCl}$ and HBr lines, respectively).

It is possible to estimate a value of the electrophilicity index, $\omega$, as defined by the conceptual DFT method [28]. This index is given in terms of the energies of the lowest energy-unoccupied and the highest energy-occupied molecular orbitals ( $E_{\mathrm{LUMO}}$ and $E_{\mathrm{HOMO}}$ ), respectively, by the expression

$$
\begin{equation*}
\omega \approx\left(E_{\mathrm{HOMO}}+E_{\mathrm{LUMO}}\right)^{2} / 8\left(E_{\mathrm{LUMO}}-E_{\mathrm{HOMO}}\right) \tag{2}
\end{equation*}
$$

When $E_{\text {LUMO }}$ and $E_{\text {HOMO }}$ are calculated at the CCSD/aug-cc-pVTZ//CCSD(T)/aug-cc-pVTZ level of theory, the results for $\omega$ are $1.97,1.31$ and 1.20 eV for $\mathrm{BeF}_{2}, \mathrm{BeH}_{2}$ and $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2}$, respectively, and $1.92,1.11$ and 1.03 eV for $\mathrm{MgF}_{2}, \mathrm{MgH}_{2}$ and $\mathrm{Mg}\left(\mathrm{CH}_{3}\right)_{2}$, respectively. Figure 9 shows a plot of the $E_{\mathrm{A}}$ values from the present work against $\omega$. There is a reasonable correlation between the two measures of the electrophilicity of the six $\mathrm{MR}_{2}$.

## 3. Theoretical Methods

The equilibrium geometries, dissociation energies, $D_{\mathrm{e}}$, and force constants, $k_{\sigma}$, were obtained at the $\operatorname{CCSD}(\mathrm{T})$ computational level [29] for each $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complex investigated. In the first step of the calculations, the geometry of the monomers and complexes was optimized with the aug-cc-pVTZ basis set [30] at the $\operatorname{CCSD}(\mathrm{T})$ level. A geometry scan of the intermolecular distance of $\pm 0.1 \AA$ from the optimized value, $r_{\mathrm{e}}$, was then determined in steps of $\left(r-r_{\mathrm{e}}\right)=$ $0.025 \AA$ at the same computational level to yield the variation of the energy $E\left(r-r_{\mathrm{e}}\right)$ with the displacement $\left(r-r_{\mathrm{e}}\right)$ from equilibrium. As an example, the resulting curve for the $\mathrm{OC} \cdots \mathrm{BeF}_{2}$ complex is given in Figure 11. Such curves were then fitted by a third-order polynomial in $\left(r-r_{\mathrm{e}}\right)$, from which $k_{\sigma}$ is obtained as the numerical value of the second derivative of $E$ with respect to $\left(r-r_{\mathrm{e}}\right)$ evaluated at $r_{\mathrm{e}}$. In order to obtain more accurate $D_{\mathrm{e}}$ values, complete basis set (CBS) extrapolation [CCSD $(T) / C B S$ energy] was executed by using the CCSD $(T) /$ aug-cc-pVTZ/ /CCSD $(T) /$ aug-cc-pVTZ and $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVQZ//CCSD $(\mathrm{T}) /$ aug-cc-pVTZ energies for all the systems [31,32]. Thus, the $D_{e}$ values have been obtained as the difference of the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ energy of the monomers and the complex. All ab initio calculations were performed with the MOLPRO-2012 program [33]. The molecular electrostatic potential surfaces of the various $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ monomers were calculated on the $0.001 \mathrm{e} /$ bohr $^{3}$ electron density isosurface at the CCSD/aug-cc-pVTZ/ /CCSD(T)/aug-cc-pVTZ level of theory by using the Gaussian-16 Program [24]. Tables 1 and 2 include the $D_{e}$ and $k_{\sigma}$ values for all complexes investigated here.

Figure 11. Variation of the energy $E\left(r-r_{\mathrm{e}}\right)$ of $\mathrm{OC} \cdots \mathrm{BeF}_{2}$ as a function of the displacement $\left(r-r_{\mathrm{e}}\right)$ from the global minimum at $r_{\mathrm{e}}$ along the $\mathrm{C}_{2}$ axis of this Y-shaped complex. ( $\mathrm{F}-\mathrm{Be}-\mathrm{F}$ ) forms the arms of the Y and CO forms the stem. See Figure 3 for a molecular diagram. The geometry was re-optimized at each of the indicated points and the line through the points is the third-order polynomial curve from the regression fit to the points. The second derivative evaluated at $r_{e}$ gives the intermolecular stretching force constant, $k_{\sigma}$. The corresponding curves and the fitted polynomials for all $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes ( $\mathrm{B}=\mathrm{CO}, \mathrm{H}_{2} \mathrm{~S}, \mathrm{PH}_{3}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{NH}_{3} ; \mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\mathrm{CH}_{3}$ ) investigated here are available in the Supplementary Material.

## 4. Conclusions

Ab initio calculations at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level have yielded the geometries, intermolecular stretching force constants, $k_{\sigma}$, and dissociation energies, $D_{\mathrm{e}}$, of the $18 \mathrm{~B} \cdots \mathrm{BeR}_{2}$ complexes $\left(\mathrm{B}=\mathrm{CO}, \mathrm{HCN}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}\right.$ or $\mathrm{PH}_{3}$ and $\mathrm{R}=\mathrm{F}, \mathrm{H}$ or $\left.\mathrm{CH}_{3}\right)$ and of the corresponding set of complexes in which Be is replaced by Mg . In all cases, $D_{e}$ was determined by using the complete basis set extrapolation. The dissociation energies, $D_{\mathrm{e}}$, reveal that, for a given R, the complexes involving Mg are more strongly bound than those involving Be-a conclusion that is consistent with the greater maximum positive MEPS for the former (see Figure 1 and Figure S1 of Supplementary

Material). It has been shown that all the complexes have a Y shape that can be understood as follows. The free $\mathrm{MR}_{2}$ molecules are linear (see Figure 2). The following process may then be envisaged. The Lewis base, $B$, is assumed to approach $M R 2_{2}$ so that the non-bonding electron pair of $B$ (the most nucleophilic region of $B$ ) interacts with the belt of high electrophilicity that lies around the M atom (see blue regions in Figure 1) to give an initially T-shaped complex. As the Lewis base becomes closer, the linear $\mathrm{R}-\mathrm{M}-\mathrm{R}$ subunit distorts, with the R atoms/groups moving away from B to give the Y shape. One might envisage the following electronic description of the process. The two valence-shell electrons of the metal atom, M , in $\mathrm{MR}_{2}$ are assumed to singly occupy $\mathrm{sp}_{z}$ hybrids, which then form single bonds with F or H or C to give the linear molecules $\mathrm{F}-\mathrm{M}-\mathrm{F}, \mathrm{H}-\mathrm{M}-\mathrm{H}$ and $\mathrm{H}_{3} \mathrm{C}-\mathrm{M}-\mathrm{CH}_{3}$, respectively. The electrophilic (relatively positive) belt around the metal atom, M , and perpendicular to the $\mathrm{F}-\mathrm{M}-\mathrm{F}$ line, is presumably a consequence of the empty $n \mathrm{p}_{x}$ and $n \mathrm{p}_{y}$ orbitals ( $n=2$ for $\mathrm{M}=\mathrm{Be}$ and $n=3$ for $\mathrm{M}=\mathrm{Mg}$ ). As the non-bonding pair of B approaches and interacts with an empty $\mathrm{p}_{x}$ or $\mathrm{p}_{y}$ orbital, the hybridization at M changes gradually to take on some $\mathrm{sp}^{m}$ character. As $m$ increases from 1 to 2, the angular deviation, $\theta$ (see Figure 3 for the definition of $\theta$ ) from linearity, should increase from $0^{\circ}$ to $30^{\circ}$, the latter corresponding to an $\mathrm{R}-\mathrm{M}-\mathrm{R}$ angle of $120^{\circ}$. We note from Tables 1 and 2 that for a given M and R , the angle, $\theta$, tends to increase as the binding strength ( $D_{\mathrm{e}}$ or $k_{\sigma}$ ) increases and about $20^{\circ}$ for the most strongly bound complexes, namely, those involving $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{NH}_{3}$ with $\mathrm{BeR}_{2}$. Moreover, the lengthening $\delta r(\mathrm{M}-\mathrm{R})$ of the $\mathrm{M}-\mathrm{R}$ bond tends to increase with binding strength. Both observations are consistent with a change from sp towards $\mathrm{sp}^{2}$ hybridization. Thus, it appears that the interaction of $B$ and $\mathrm{MR}_{2}$ can be described as partly electrostatic and partly dative in character. It is noted that the dative bond character appears greater when $M=B e$ than when $M=M g$, with the non-linearities $\theta$ closer to $30^{\circ}$, with larger values of $\delta r(\mathrm{M}-\mathrm{R})$ and presumably values of $m$ closer to 2 in the $\mathrm{sp}^{m}$ hybridization scheme. It appears, therefore, that these are not purely $\sigma$-hole/n-pair interactions.

The shapes of the $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes can be predicted by a simple modification to a rule recently enunciated [20] for tetrel-bonded complexes of the type $\mathrm{B} \cdots \mathrm{CO}_{2}$, that is:

The equilibrium geometry of alkaline-earth bonded $\mathrm{B} \cdots \mathrm{MR}_{2}$ complexes $(\mathrm{M}=\mathrm{Be}, \mathrm{Mg} \ldots$ ) can be predicted by assuming that a radius of the most electrophilic ring around the M atom that is perpendicular to the $\mathrm{MR}_{2}$ line coincides with the axis of a non-bonding electron pair carried by B . Some deviation of $\mathrm{MR}_{2}$ from collinearity could occur.
For both sets of $\mathrm{B} \cdots \mathrm{BeR}_{2}$ and $\mathrm{B} \cdots \mathrm{MgR}_{2}$ complexes, it has been established that $D_{\mathrm{e}}$ is directly proportional to $k_{\sigma}$ to a good degree of approximation, as seen from Figures 6 and 7. Moreover, as with more weakly bound complexes such as $\mathrm{B} \cdots \mathrm{HX}(\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br})$, it has been possible to partition $D_{\mathrm{e}}$ into contributions from the individual molecules B and $\mathrm{MR}_{2}$, called the nucleophilicity, $N_{\mathrm{B}}$, of the Lewis base, $B$, and the electrophilicity, $E_{\mathrm{A}}$, of the Lewis acid, A , respectively. As may be seen from Table 3, the order of the $E_{\mathrm{A}}$ values for both $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ sets when acting as Lewis acids is $\mathrm{R}=$ $\mathrm{F}>\mathrm{H} \geq \mathrm{CH}_{3}$, which is the order expected from the -I inductive effect of F relative to H and the +I effect of the $\mathrm{CH}_{3}$ group relative to H , and is the order indicated by the MEPS in Figure 1. The - I effect of F is evidently greater than the +I effect of $\mathrm{CH}_{3}$. It is also clear from Table 3 that for a given R , the electrophilicity of $\mathrm{BeR}_{2}$ is greater than that of $\mathrm{MgR}_{2}$. This appears to be at variance with the MEPS, because the electrophilic (blue) belt around M is more positive for $\mathrm{M}=\mathrm{Mg}$ than Be , with, for example, the maximum positive potentials for $\mathrm{MgF}_{2}$ and $\mathrm{BeF}_{2}$ at 753 and $337 \mathrm{~kJ} \mathrm{~mol}{ }^{-1}$, respectively (see Figure 1 and Introduction). It is of interest that the order of electrophilicities given in Table 3 is $\mathrm{BeF}_{2}>\mathrm{BeH}_{2} .>$ $\mathrm{Be}\left(\mathrm{CH}_{3}\right)_{2} \sim \mathrm{MgF}_{2}>\mathrm{MgH}_{2}>\mathrm{Mg}\left(\mathrm{CH}_{3}\right)_{2} \gg \mathrm{HF}>\mathrm{HBr} \sim \mathrm{HCl}$, which indicates just how effective $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ are as Lewis acids. Various other scales of nucleophilicity and electrophilicity have been proposed. Some are based on the rate constants for organic reactions in solution [34], while others have been based on conceptual density functional theory (CDFT) [28]. A comparison of our results for the $E_{\mathrm{A}}$ of $\mathrm{MR}_{2}$ with those estimated by the CDFT approach has been presented.

We have shown that the $\mathrm{BeR}_{2}$ and $\mathrm{MgR}_{2}$ Lewis acids discussed here undergo non-covalent interactions with a series of Lewis bases, all of which can provide a non-bonding electron pair to interact with the electrophilic belt that encircles the central metal atom in $\mathrm{MR}_{2}$. Evidently, these interactions
can be described as beryllium bonds and magnesium bonds, respectively, by analogy with the recent definitions $[6,7,18]$ of other non-covalent interactions such as halogen-, tetrel-, pnictogen-, chalcogenand coinage-metal bonds. Therefore, we propose the following definition:

> A alkaline-earth non-covalent bond occurs when there is evidence of a net attractive interaction between an electrophilic region associated with an atom of an element, $\mathrm{E}\{\mathrm{II}\}$, in a molecular entity and a nucleophilic region (e.g., a n-pair or $\pi$-pair of electrons) in another, or the same, molecular entity, where $\mathrm{E}\{\mathrm{II}\}$ is an element of Group II in the periodic table.

Note that this definition is coherent with the IUPAC definition of the halogen bond [7].
Supplementary Materials: The following are available online at http:/ /www.mdpi.com/2304-6740/7/3/35/s1, Figure S1: Molecular electrostatic surface potentials of the linear, non-polar molecules, $\mathrm{MgF}_{2}, \mathrm{MgH}_{2}$ and $\mathrm{Mg}\left(\mathrm{CH}_{3}\right)_{2}$ calculated at the $0.001 \mathrm{e} /$ bohr $^{3}$ electron density isosurface at the CCSD/aug-cc-pVTZ//CCSD(T)/aug-cc-pVTZ level of theory, Table S1: Optimized geometry, electronic energy and Variation of the energy $E\left(r-r_{\mathrm{e}}\right)$ as a function of the displacement $\left(r-r_{\mathrm{e}}\right)$ from the global minimum at $r_{\mathrm{e}}$ at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ computational level.

Author Contributions: The conceptualization of the project, the calculations, the writing of the manuscript, the drawing of figures, checking of proofs, etc. were shared between I.A. and A.C.L.

Funding: This research was funded by Consejería de Educación e Investigación de la Comunidad de Madrid (P2018/EMT-4329 AIRTEC-CM) and Ministerio de Ciencia, Innovación y Universidades (PGC2018-094644-B-C22).

Acknowledgments: I.A. thanks Consejería de Educación e Investigación de la Comunidad de Madrid (P2018/EMT-4329 AIRTEC-CM) and Ministerio de Ciencia, Innovación y Universidades (PGC2018-094644-B-C22). A.C.L. thanks the University of Bristol for a Senior Research Fellowship.

Conflicts of Interest: The authors declare no conflict of interest.
