Abstract: Novel vitamin E chelate siderophore derivatives and their V^V and Fe^{III} complexes have been synthesised and the chemical and biological properties have been evaluated. In particular, the α - and δ -tocopherol derivatives with bis-methylhydroxylamino triazine (α -tocTHMA) and (δ -tocDPA) as well their V^V complexes, [V₂^VO₃(α -tocTHMA)₂] and [V₂^{IV}O₃(δ -tocTHMA)₂], have been synthesised and characterised by infrared (IR), nuclear magnetic resonance (NMR), electron paramagnetic resonance (EPR) and ultra violet-visible (UV-Vis) spectroscopies. The dimeric vanadium complexes in solution are in equilibrium with their respective monomers, H₂O + [V₂^VO₂(μ -O)]⁴⁺ = 2 [V^VO(OH)]²⁺. The two amphiphilic vanadium complexes exhibit enhanced hydrolytic stability. EPR shows that the complexes in lipophilic matrix are mild radical initiators. Evaluation of their biological activity shows that the compounds do not exhibit any significant cytotoxicity to cells.

Keywords: vanadium; vitamin E; EPR; tocopherol; ⁵¹V NMR

1. Introduction

The understanding of the physiological role of vanadium ions in biological systems as well as the biological activity of vanadium compounds have stimulated the interest of the scientific community towards the vanadium chemistry [1–8]. Pharmaceuticals based on vanadium complexes have attracted the interest of scientists due to the biological activity of vanadium molecules and their low toxicity [4,5,9–19]. In addition, vanadium compounds exert antitumor effects through activation of apoptotic pathways, cell cycle arrest and the generation of Reactive Oxygen Species (ROS), inducing lower toxicity than anticancer platinum-based molecules [4,20–25].

α -Tocopherol acts in biological organisms as a strong lipophilic antioxidant, without any other biological activity. However, the vitamin E (tocopheryl and tocotrienyl) derivatives, such as α -tocopheryl succinate, have anticancer properties [26–34]. The hydrophobic domain of the vitamers of vitamin E is responsible for docking the agents in circulating lipoproteins and biological membranes [35]. Conjugate molecules of vitamin E vitamers with pharmaceuticals, such as metal complexes, can be used to transfer the drug in the active site of vitamin E vitamers, inducing biological responses.

Recently, we reported the first study of the synthesis of complexes comprising tocopherol ligating to metals [36]. The ligands in this study are β -tocopherol molecules substituted with chelate groups in *o*-position derivatives (Scheme 1, H₃ β -tocDEA), thus, enabling coordination of the metal ion from the phenolic oxygen. The [V^VO(β -tocDEA)] has been found to be cytotoxic to cancer cells. Some of the features of these amphiphilic

Scheme 1. Hydroxylamino-triazine ligands and $\text{H}_3\beta$ -tocDEA. RO- is α - or δ -tocopherol. The donor atoms for metal ion coordination are in red colour.

Herein, we have attached a siderophore moiety on the phenoxy oxygen of the chromanol (Scheme 1), forming two new ligands, the 2,4-dichloro-6-(((R)-2,5,7,8-tetramethyl-2-((4R,8R)-4,8,12-trimethyltridecyl)chroman-6-yl)oxy)-1,3,5-triazine ($\text{H}_2\alpha$ -tocTHMA) and 2,4-dichloro-6-(((R)-2,8-dimethyl-2-((4R,8R)-4,8,12-trimethyltridecyl)chroman-6-yl)oxy)-1,3,5-triazine ($\text{H}_2\delta$ -tocTHMA). The labile hydrogen atom of the hydroxy group has been replaced with the triazine moiety forming an inert ether bond and, thus, the new organic molecules will act as ligand owing lower antioxidant activity than free tocopherols; the formation of the tocopheryl radical requires deprotonation of chromanol group. In addition, the high lipophilicity of both the tocopherol derivatives and their complexes assures easy penetration in cell membranes [38]. As chelate group for V^{V} we have chosen the siderophore hydroxylamino-triazine (Scheme 1), targeting to enhance the hydrolytic stability of the V^{V} complexes as much as possible. This chelate group, for example in the ligand H_2 bihyat (Scheme 1) forms very strong complexes with hard acids such as Fe^{III} , V^{V} , Mo^{VI} and U^{VI} [41–44], with Fe^{III} and U^{VI} to exert the higher affinity for this chelate coordination. The V^{V} complexes of this study exhibiting a chromanol hydroxy group unavailable for coordination, present no significant toxicity to cells. These results are in contrast to the high toxicity of the previous reported vanadium complexes, in which the vanadium ion was coordinated directly with the hydroxy group of the chromanol [36].

2. Experimental Section

2.1. Reagents

All reagents were purchased from Aldrich and Merck, (Kenilworth, NJ, USA). Vanadium complexes used for cell viability studies were dissolved in dimethyl sulfoxide (DMSO). DMSO was also used as vehicle control. Microanalyses for C, H and N were performed using a Euro-Vector EA3000 CHN elemental analyser (Milan, Italy). Infrared (IR) spectra were recorded on a Shimadzu Prestige 21, 7102 Riverwood Drive, Columbia, Maryland 21046, U.S.A. MALDI-TOF mass spectra were recorded on a Bruker Autoflex III Smartbeam (Billerica, MA, USA) instrument using α -Cyano-4-hydroxycinnamic acid (HCCA) as matrix.

2,2'-((2-hydroxyoctadecyl)azanediyl)bis(ethan-1-ol) (**C18DEA**), [$\text{V}^{\text{V}}\text{O}(\text{C18DEA})$] were prepared according to reference [37].

2.2. Synthesis

2,4-dichloro-6-(((R)-2,5,7,8-tetramethyl-2-((4R,8R)-4,8,12-trimethyltridecyl)chroman-6-yl)oxy)-1,3,5-triazine (H₂α-tocTCL). Cyanuric chloride (1.86 g, 10.0 mmol) and *N,N*-diisopropylethylamine (1.45 g, 11.2 mmol) were dissolved in 40 mL of THF. The resulting colourless solution cooled at 0 °C. A THF solution (5 mL) of α-tocopherol (4.31 g, 10.0 mmol) was added to the above solution. The yellow solution was stirred for 24 h at room temperature. Then, the solution was evaporated, and the residue was extracted with chloroform/water. The organic phase was evaporated to give a yellow-orange oil as the product (3.50 g, 61%). ¹H-NMR, (300 MHz, CDCl₃) δ ppm: 0.85–0.88 (m, 12H, -CH₃ methyl groups of the tocopherol), 1.12–1.15 (m, 6H), 1.26 (br s, 10H), 1.35–1.46 (m, 5H), 1.50–1.58 (m, 3H), 1.80–1.85 (m, C16-H), 1.95–1.99 (d, C8-H, C14-H), 2.12 (s, C10-H), 2.60–2.64 (t, C15-H). Elemental Analysis for C₃₂H₄₉C₁₂N₃O₂: Found: C, 66.20; H, 8.88; N, 7.13, Calcd.: C, 66.42; H, 8.54; N, 7.26.

2,4-dichloro-6-(((R)-2,8-dimethyl-2-((4R,8R)-4,8,12-trimethyltridecyl)chroman-6-yl)oxy)-1,3,5-triazine (H₂δ-tocTCL). Cyanuric chloride (1.95 g, 10.6 mmol) was dissolved in 40 mL of THF with the dropwise addition of *N,N*-diisopropylethylamine (1.50 g, 11.6 mmol) and the solution cooled at 0 °C. To the resulting solution, equivalent quantity of δ-tocopherol (4.26 g, 10.6 mmol) dissolved in 5 mL of THF was added. The solution was left to stir for 24 h at room temperature and the colour of the solution changed to yellow. The next day the solution was evaporated and extracted with chloroform/water. The chloroform extract was evaporated to give a yellow-orange oil as the product (3.00 g, 52%). ¹H-NMR, (300 MHz, CDCl₃) δ ppm: 0.87–0.90 (m, 12H, -CH₃ methyl groups of the tocopherol), 1.10–1.16 (m, 6H), 1.31 (br s, 10H), 1.36–1.45 (m, 5H), 1.52–1.61 (m, 3H), 1.80–1.87 (m, C16-H), 2.16 (s, C10-H), 2.72–2.83 (t, C15-H). Elemental analysis for C₃₀H₄₅C₁₂N₃O₂: Found: C, 65.31; H, 8.33; N, 7.28, Calcd.: C, 65.44; H, 8.24; N, 7.63.

Synthesis of N,N'-(6-(((R)-2,5,7,8-tetramethyl-2-((4R,8R)-4,8,12-trimethyltridecyl)chroman-6-yl)oxy)-1,3,5-triazine-2,4-diyl)bis(*N*-methylhydroxylamine) (H₂α-tocTHMA). **1st method:** α-tocTCL (3.00 g, 5.18 mmol) was dissolved in THF (120 mL) at 0 °C. A cooled (0 °C) solution of *N*-Methylhydroxylamine hydrochloride (1.80 g, 21.5 mmol) and sodium hydroxide (0.86 g, 2.2 mmol) in water (10 mL) was added dropwise in the above solution. The reaction mixture was refluxed for 24 h. Then, the solution was evaporated under vacuum to dry, and the residue was extracted with chloroform/water. The organic phase was evaporated under vacuum to dry resulting in H₂α-tocTHMA as an orange-brown oil. The yield was 2.1 g, 68%.

2nd method: α-tocTCL (3.00 g, 5.18 mmol) was dissolved in THF (120 mL) at 0 °C. A cooled (0 °C) solution of *N*-Methylhydroxylamine hydrochloride (1.80 g, 21.5 mmol) and sodium hydroxide (0.86 g, 2.2 mmol) in water (10 mL) was added dropwise to the above solution. The reaction mixture was kept under stirring at room temperature for 4 days. Then, it was evaporated under vacuum to dry, and the residue was dissolved in chloroform and filtrated to remove the insoluble in chloroform NaCl. The solution was evaporated under vacuum to dry yielding H₂α-tocTHMA, 2.0 g, 66% as an orange-brown oil. ¹H-NMR, (300 MHz, CDCl₃) δ ppm: 0.85–0.90 (m, 12H methyl groups of tocopherol), 1.14–1.17 (m, 6H), 1.25–1.27 (br s, 10H), 1.35–1.46 (m, 5H), 1.50–1.57 (m, 3H), 1.79–1.84 (m, C16-H), 1.96–2.00 (d, C8-H, C14-H), 2.11–2.13 (s, C10-H), 2.59–2.62 (t, C15-H), 3.3–2.5 (s, 6H methyl groups of *N*-methylhydroxylamine). Elemental Analysis for C₃₄H₅₇N₅O₄: Found: C, 68.29; H, 9.31; N, 11.59, Calcd.: C, 68.08; H, 9.58; N, 11.68. [MALDI-TOF(+)-MS]: calcd for (C₃₄H₅₇N₅O₄Na) {[M + Na]⁺} *m/z* 622.43, found 623.13 (100%).

Synthesis of N,N'-(6-(((R)-2,8-dimethyl-2-((4R,8R)-4,8,12-trimethyltridecyl)chroman-6-yl)oxy)-1,3,5-triazine-2,4-diyl)bis(*N*-methylhydroxylamine) (H₂δ-tocTHMA). H₂δ-tocTHMA was synthesised following the same methodology as for the synthesis of H₂α-tocTHMA. The yields were 82% and 53% for the 1st and the 2nd synthetic methods respectively. ¹H-NMR, (300 MHz, CDCl₃) δ ppm: 0.87–0.90 (m, 12H methyl groups of tocopherol), 1.08–1.19 (m, 6H), 1.26–1.29 (br s, 10H), 1.36–1.48 (m, 5H), 1.52–1.57 (m, 3H), 1.79–1.81 (t, C16-H), 2.14–

2.17 (d, C10-H), 2.70–2.75 (t, C15-H), 3.3–2.5 (s, 6H methyl groups of *N*-methylhydroxylamine), 6.40–6.75 (2 dd, H-aromatic C7, C13). Elemental analysis for $C_{32}H_{53}N_5O_4$: Found: C, 67.11; H, 9.18; N, 12.07, Calcd.: C, 67.22; H, 9.34; N, 12.25. [MALDI-TOF(+)-MS]: calcd for $(C_{32}H_{53}N_5O_4Na) \{[M + Na]^+\}$ m/z 594.37, found 595.18 (100%).

Synthesis of $[V^V_2O_2(\mu-O)(\alpha\text{-tocTHMA})_2]$, 1. 1st Method: $V^{IV}OSO_4 \cdot 5H_2O$ (0.13 g, 0.49 mmol) was stirred in 35 mL MeOH at 35 °C, under nitrogen. Then, $H_2\alpha\text{-tocTHMA}$ (0.29 g, 0.49 mmol) dissolved in the minimum amount of methanol, was added to the above methanolic solution resulting in a deep brown solution. The solution was stirred for 24 h at room temperature. Then, it was filtered to remove any precipitation, and the filtrate was kept at room temperature for 5 days. During that time a black solid of **1** was formed, which was filtered and dried under vacuum. The yield was 65 mg, 20%.

2nd Method: $\alpha\text{-tocTHMA}$ (1.2 g, 2.0 mmol) dissolved in the minimum amount of methanol was added to a stirring methanol solution (40 mL) of $[V^{IV}O(\text{acac})_2]$ (0.53 g, 2.0 mmol) under nitrogen. The dark brown solution was stirring at room temperature for 10 min. Then, the solution was filtered, and the filtrate was left unstirred for 5 days, under air, at room temperature. During that time a black solid of **1** was formed which was filtered and dried under vacuum. The yield was 0.35 g, 26%. FTIR (ATR, cm^{-1}): 2924 (C-H), 1580 (C = N_{triazine}), 1524 (ar C-C), 1094 (N-O), 966 (V=O), 798 (V-O-V). Elemental analysis for $C_{68}H_{110}N_{10}O_{11}V_2$: Found: C, 60.47.11; H, 8.32; N, 10.10, Calcd.: C, 60.70; H, 8.24; N, 10.41. [MALDI-TOF(+)-MS]: calcd for $(C_{34}H_{55}N_5Na_2O_6V) \{[M-O-M (-M+2Na)]^+\}$ m/z 726.34, found 727.19 (100%).

Synthesis of $[V^V_2O_2(\mu-O)(\delta\text{-tocTHMA})_2]$, 2. Similar with **1** synthetic methodologies were used for the synthesis of **2**. The yields were 24% and 19% for the 1st and the 2nd synthetic methods respectively. FTIR (ATR, cm^{-1}): 2928 (C-H), 1578 (C = N_{triazine}), 1526 (ar C-C), 1070 (N-O), 964 (V=O), 798 (V-O-V). Elemental analysis for $C_{64}H_{102}N_{10}O_{11}V_2$: Found: C, 59.45; H, 7.83; N, 10.47, Calcd.: C, 59.61; H, 7.97; N, 10.86. [MALDI-TOF(+)-MS]: calcd for $(C_{32}H_{52}N_5Na_2O_6V) \{[M-O-M (-M + 2Na)]^+\}$ m/z 698.31, found 699.30 (100%).

Synthesis of $[Fe^{III}(\alpha\text{-tocTHMA})(H\alpha\text{-tocTHMA})]$, 3. Ferric chloride (0.03 g, 0.20 mmol) was dissolved under Ar in 20 mL MeOH forming a yellow solution. $H_2\alpha\text{-tocTHMA}$ (0.24 g, 0.40 mmol) dissolved in the minimum amount of methanol was added in the above yellow solution, resulting in a deep blue solution. The solution was filtered, and the filtrate cooled at -18 °C resulting in a black precipitate of **3** which was filtered and dried under vacuum. The yield was 120 mg, 24%. Elemental analysis for $C_{68}H_{111}FeN_{10}O_8$: Found: C, 65.11; H, 8.89; N, 10.95, Calcd.: C, 65.21; H, 8.93; N, 11.18. [MALDI-TOF(+)-MS]: calcd for $(C_{34}H_{55}N_5O_4Fe) \{[M-L]^+\}$ m/z 653.36, found 654.31 (100%).

Synthesis of $[Fe^{III}(\delta\text{-tocTHMA})(H\delta\text{-tocTHMA})]$, 4. Complex **4** was synthesised using the same methodology as the one used for **3**. The yield was 105 mg, 22%. Elemental analysis for $C_{64}H_{103}FeN_{10}O_8$: Found: C, 64.09; H, 8.81; N, 11.69, Calcd.: C, 64.25; H, 8.68; N, 11.71. [MALDI-TOF(+)-MS]: calcd for $(C_{32}H_{51}N_5O_4Fe) \{[M-L]^+\}$ m/z 625.33, found 626.19 (100%).

2.3. Spectroscopic Studies

All NMR samples were prepared from the dissolution of the solids in $CDCl_3$ or 10% $DMSO-d_6$:90% D_2O at room temperature immediately before NMR spectrometric determinations. NMR spectra were recorded on a Bruker Avance 300 spectrometer at 300 MHz for 1H , 75.4 MHz for ^{13}C and 78.9 MHz for ^{51}V NMR. A 30°-pulse width was applied for both the 1H and ^{51}V NMR measurements, and the spectra were acquired with 3000 and 30,000 Hz spectral window, using 1 and 0.1 s relaxation delay respectively. The spectra were analysed using Topspin 4.0 and MultispecNMR 5.0 (<https://sourceforge.net/projects/multispecnmr/>, accessed on 1 March 2021). 2D [45] *gr*NOESY spectra were obtained by using standard pulse sequences of Bruker Topspin 3.0 software. These spectra were acquired using 256 increments (with 56 scans each) and mixing time 0.43 s.

UV-Vis measurements were recorded on a Photonics UV-Vis spectrophotometer Model 400, equipped with a CCD array, operating in the range 250 to 1000 nm. The spectra were

analysed using MultispecUVVIS 5.0 (<https://sourceforge.net/projects/multispecuvvis/>, accessed on 1 March 2021).

2.4. Reactivity with DPPH•

The rate of DPPH• consumption was measured by UV-vis spectroscopy at 520 nm for 30 min. Stock solutions of each compound (12 mM) were prepared in dry toluene at room temperature. The final concentrations of the compounds were 80–300 µM, while the concentration of DPPH• was 100 µM. The samples were incubated at 25 °C for 4 min. The reaction was initiated by the addition of the DPPH• solution. The samples were measured in triplicate. Second-order rate constants were calculated to determine the radical scavenging activity (RSC) of antioxidants. The decay of DPPH• from the medium has been assumed to follow pseudo-first-order kinetics, under the conditions of the reaction $[DPPH^{\bullet}]_0$, $[AH]_0$. One of the reactants is in large excess compared to the other, so the concentration of the minor component decreased exponentially [46]. The $[DPPH^{\bullet}]$ concentration is calculated from Equation (1):

$$[DPPH^{\bullet}] = [DPPH^{\bullet}]_0 e^{-k_{\text{obsd}} t} \quad (1)$$

where $[DPPH^{\bullet}]$ is the radical concentration at time t , and $[DPPH^{\bullet}]_0$ is the radical concentration at time zero, and k_{obsd} is the pseudo-first-order rate constant. The pseudo-first-order rate constant k_{obsd} was linearly dependent on the concentration of antioxidants $[AH]$, and from the slope of their plot, second-order rate constants (k_2) were calculated to evaluate the radical scavenging capacity of each compound.

2.5. Measurement of Oxidative Inducing Effect of Vanadium Compounds by EPR Spectroscopy

An ELEXSYS E500 Bruker EPR spectrometer operating at cw X-band, resonance frequency ~9.5 GHz and modulation frequency 100 MHz was used. The resonance frequency was accurately measured with solid DPPH ($g = 2.0036$). The EPR oxidative inducing effect experiments were conducted by monitoring the evolution of α -tocopheryl radicals versus time [37] at room temperature. The assays were prepared in a 5 mm quartz tube by adding 100 µL or 150 µL of a $CHCl_3$ stock solution (4.95 mM) of complex to 0.500 g of a commercial extra virgin olive oil. Radical initiators are the **1**, **2** and $[VO(C18DEA)]$ whereas the addition step consists of the initial time of the reaction, time = 0 min. EPR spectra were recorded for 25- or 30-time domains, each one consisting of 50 scans. The spectra were processed using appropriate software, MultispecEPR 5.0 (<https://sourceforge.net/projects/multispecepr/>, accessed on 1 March 2021).

2.6. Cell Culture

The human tongue squamous cell carcinoma (Cal33, DSMZ[®] ACC 447), the human cell line derived from cervical cancer (HeLa, ATCC[®] CCL-2) and the embryonic mouse fibroblasts (NIH/3T3, CRL-1658[™]) were used in this study [47]. Cells were grown in monolayer cultures in high glucose Dulbecco's modified eagle medium (DMEM) supplemented with 10% (v/v) foetal bovine serum, 2 mM L-glutamine and 1% (v/v) penicillin-streptomycin (100×: 10,000 units/mL of penicillin and 10,000 µg/mL streptomycin) in a humidified incubator (5% CO_2 , 95% air) at 37 °C.

2.7. Measurement of Cell Viability

Cells were plated in 96-well plates at density 5×10^3 cells/well and treated with the ligands or the complexes for 24 and 48 h. Cell viability was measured after incubation of each well with 50 µL of MTT (stock solution of 3 mg/mL) for 3 h and absorbance was determined at 570 nm (background absorbance measured at 690 nm) using a microplate spectrophotometer (Multiskan Spectrum, Thermo Fisher Scientific, Waltham, MA, USA). All experiments were performed in triplicate.

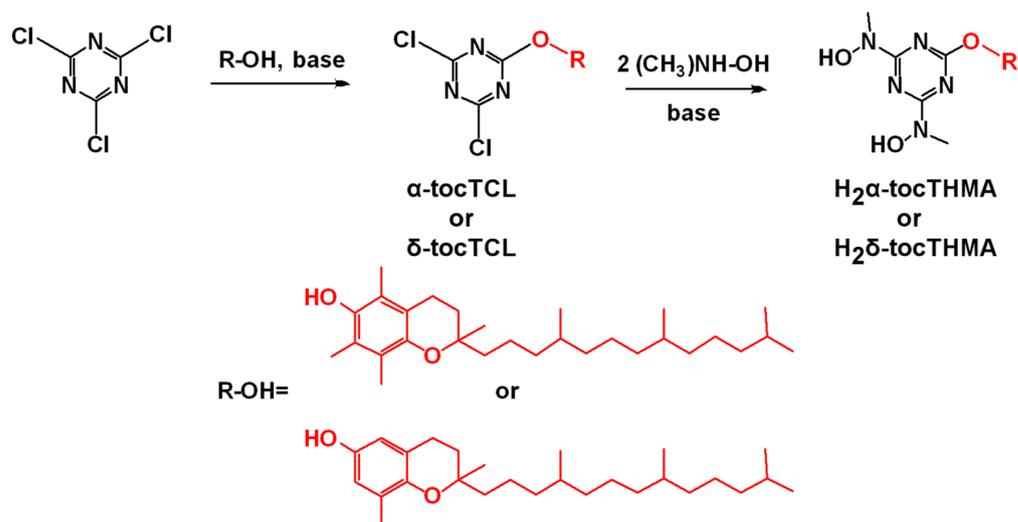

Stock solutions of $H_2\alpha$ -tocTHMA and $H_2\delta$ -tocTHMA and **1–4** prepared in pure DMSO were diluted into the culture medium so that the final concentration of DMSO was less

than 1%. The same amount of DMSO was added to the control sample. Stock solutions were kept at 4 °C.

3. Results and Discussion

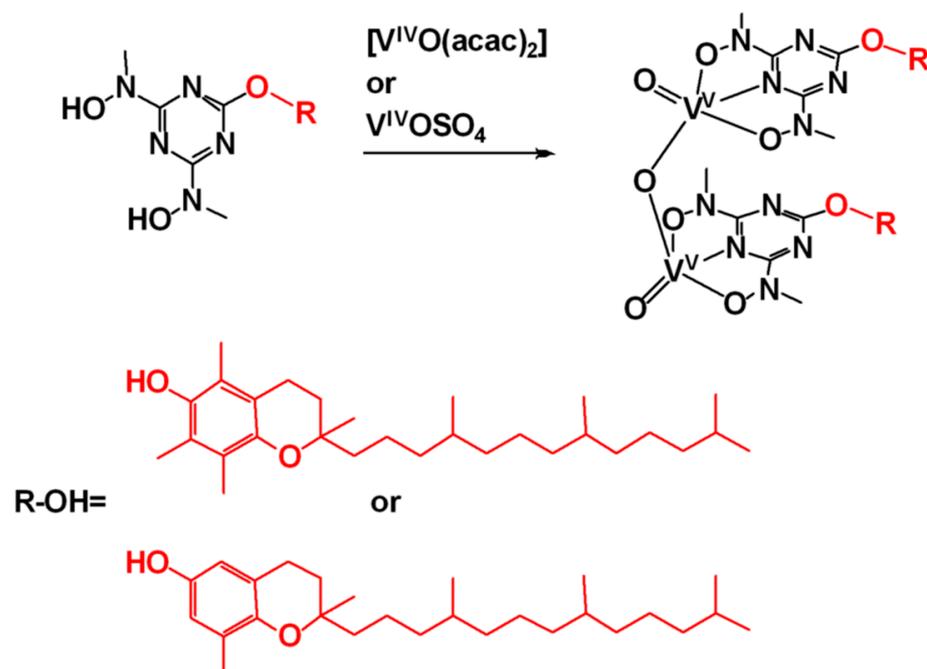

3.1. Synthesis and Characterisation

The triazine tocopherol molecules H₂α-tocTHMA and H₂δ-tocTHMA were synthesized by two-step substitution reactions of cyanuric chloride. The synthetic process is summarised in Scheme 2.

Scheme 2. Synthetic route for the organic compounds.

Reaction of equimolar quantities of H₂α-tocTHMA or H₂δ-tocTHMA with [V^{IV}O(acac)₂] or V^{IV}OSO₄ results in the formation of V^V complexes 1 and 2 (Scheme 3). The V^{IV} is oxidised to V^V by the atmospheric O₂. X-band EPR spectroscopy of frozen CHCl₃ solutions of either 1 or 2 did not exhibit any signal supporting that all V^{IV} has been oxidised to V^V.

Scheme 3. Synthetic route for the vanadium complexes.

The complexes were characterised by elemental analysis, UV-vis, IR and NMR spectroscopies. The structures of the vanadium complexes are based on the data of the experimental analysis and the X-ray structures of the respective V^V -bihyat²⁻ complexes [42].

3.2. Complexes Characterisation by IR

The IR spectra of **1** and **2** are shown in Figure 1. Both **1** and **2** gave a strong peak at 966 cm^{-1} attributed to the stretching of the V=O bond. The peaks at 798 cm^{-1} are characteristic to V-O-V stretching vibrations [48,49], thus, confirming the dinuclear structure of the complex. The complexes also show two strong stretching N-O vibrations shifted around 80 cm^{-1} at higher energy compared to the free ligand suggesting coordination of the metal ion from the hydroxylamine-triazazine chelating group.

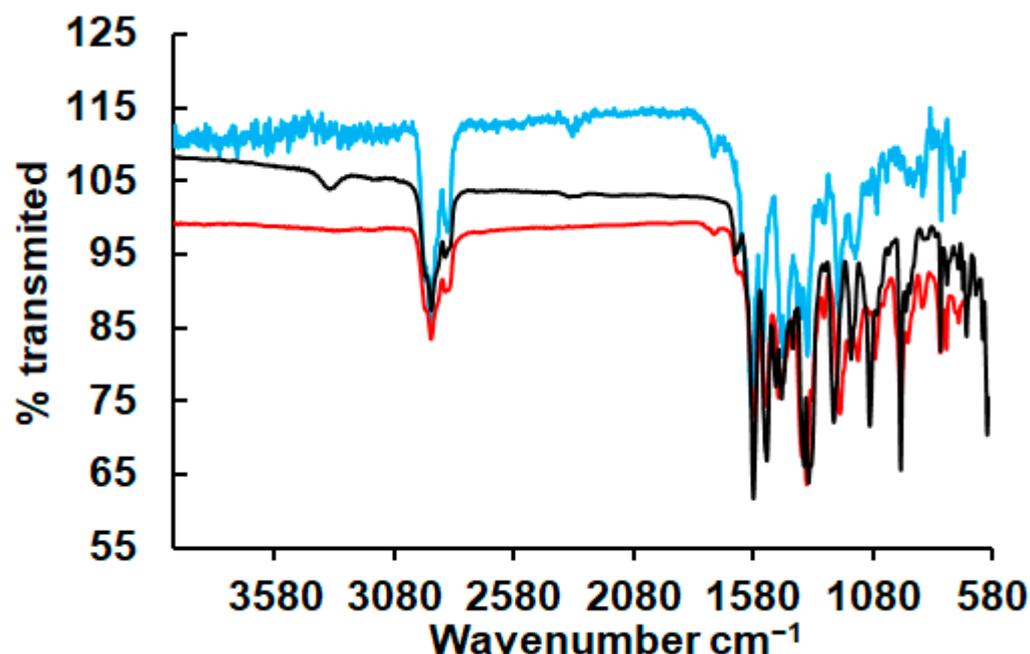

Figure 1. IR spectra of: **1** [$\nu(\text{V}=\text{O})$, 966 cm^{-1} ; (C=N triazine), 1579 , 1529 cm^{-1} ; (Ph-O), 1242 cm^{-1} ; (N-O), 1092 cm^{-1} ; 798 (V-O-V)] (black line), **2** [$\nu(\text{V}=\text{O})$, 966 cm^{-1} ; (C=N triazine), 1579 , 1529 cm^{-1} ; (Ph-O), 1240 cm^{-1} ; (N-O), 1084 cm^{-1} ; 798 (V-O-V)] (red line), **3** [(C=N triazine), 1569 , 1525 cm^{-1} ; (Ph-O), 1244 cm^{-1} ; (N-O), 1093 cm^{-1}] (blue line).

The IR spectra of the complexes **3** and **4** gave peaks at 2952 , 2924 and 2896 cm^{-1} assigned to the C-H stretching of lipid chains. The C=N ring vibrations show peaks at 1569 and 1525 cm^{-1} whereas Ph-O and N-O stretching vibrations were detected at 1244 and 1093 cm^{-1} respectively. The N-O peaks are significantly shifted compared to the free ligand ($\sim 70\text{ cm}^{-1}$) due to the ligation of the ligand to Fe^{III} .

3.3. Complex Characterisation by ^{51}V NMR, 2D $\{^1\text{H}\}$ grNOESY

The ^{51}V spectra of each of the V^V complexes (**1**, **2**) in CDCl_3 solutions gave two signals at -216 and -387 ppm (Figure 2). The intensity of the peaks is dependent on the concentration of the complexes in solution. At low concentration (i.e., 1 mM) the component at -216 ppm is the major, whereas at more concentrated solutions (i.e., 7 mM) the spectra of each of the complexes shows only the peak at -387 ppm . For more concentrated solutions three broad additional peaks of equal intensity appear at higher field (-402 , -439 and -648 ppm), presumably originated from a higher nuclearity compound. The ^{51}V NMR spectra changes observed by the variation of the concentration are attributed to the equilibrium between the monomer (**1m**), dimer (**1**) and oligomers (Scheme 4). The quantities of **1m** and **1** are equal at concentration 2.5 mM , calculating a $K_{\text{eq}} = [\mathbf{1m}^2]/[\mathbf{1}] = 1.25 \times 10^{-3}\text{ M}$. The conversion of the **1** to **1m** species takes approximately 2 min after the dissolution

of **1** in CDCl_3 , and it can be observed by the change of the colour of the solution from purple to blue. Dimerization of the hydroxylamine-triazine ligands through the formation of M-O-M bridge has been previously observed for U^{VI} -, Mo^{VI} - and V^{V} -bihyat²⁻ complexes [42,43]. The respective ^{51}V NMR spectrum of CDCl_3 solution of the structurally characterised by single crystal X-ray dinuclear complex $[\text{V}^{\text{V}}_2\text{O}_2(\mu_2\text{-O})(\text{bihyat})_2]$ exhibits peaks at -192 , -402 and -485 ppm. However, the ^{51}V NMR peaks of the CDCl_3 solution of $[\text{V}^{\text{V}}_2\text{O}_2(\mu_2\text{-O})(\text{bihyat})_2]$ at -192 ppm had been mistakenly attributed to the decomposition of the compound.

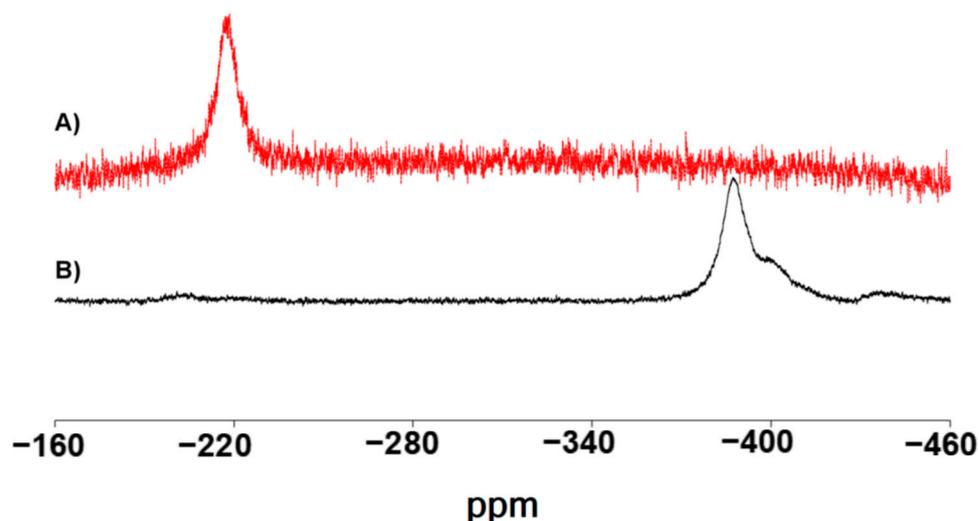

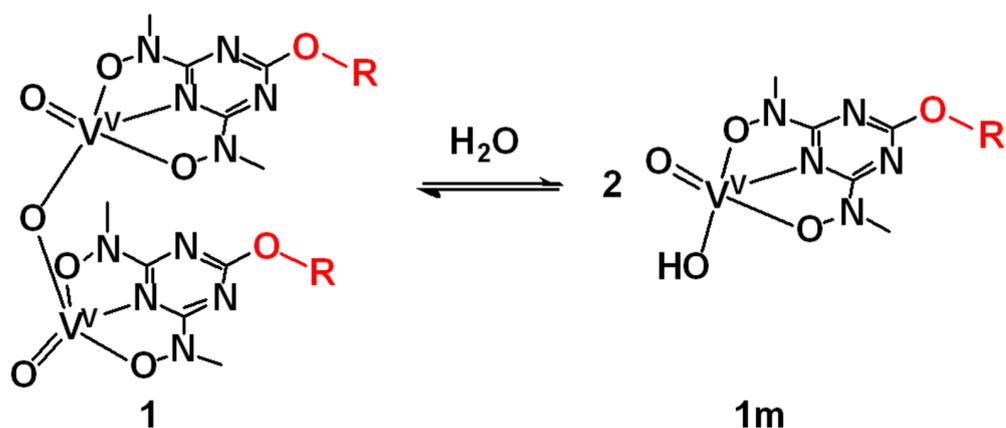

Figure 2. ^{51}V NMR spectra of CD_3Cl solutions of **1**, (A) 1.00 mM (B) 7.00 mM.

Scheme 4. Equilibrium between the monomer, **1m** and the dimer, **1**.

The 2D $\{^1\text{H}\}$ grNOESY of **1** is shown in Figure 3. The two methyl groups show difference in chemical shifts due to the different chemical environment. 2D $\{^1\text{H}\}$ grNOESY shows positive cross peaks between the protons of the two methyl groups assigned to the slow rotation methylhydroxylamine giving two peaks at 2.869 and 2.573 ppm in proton NMR. The rotation of tocopherol is performed around the ether bond between tocopherol and triazine moieties (Figure 3).

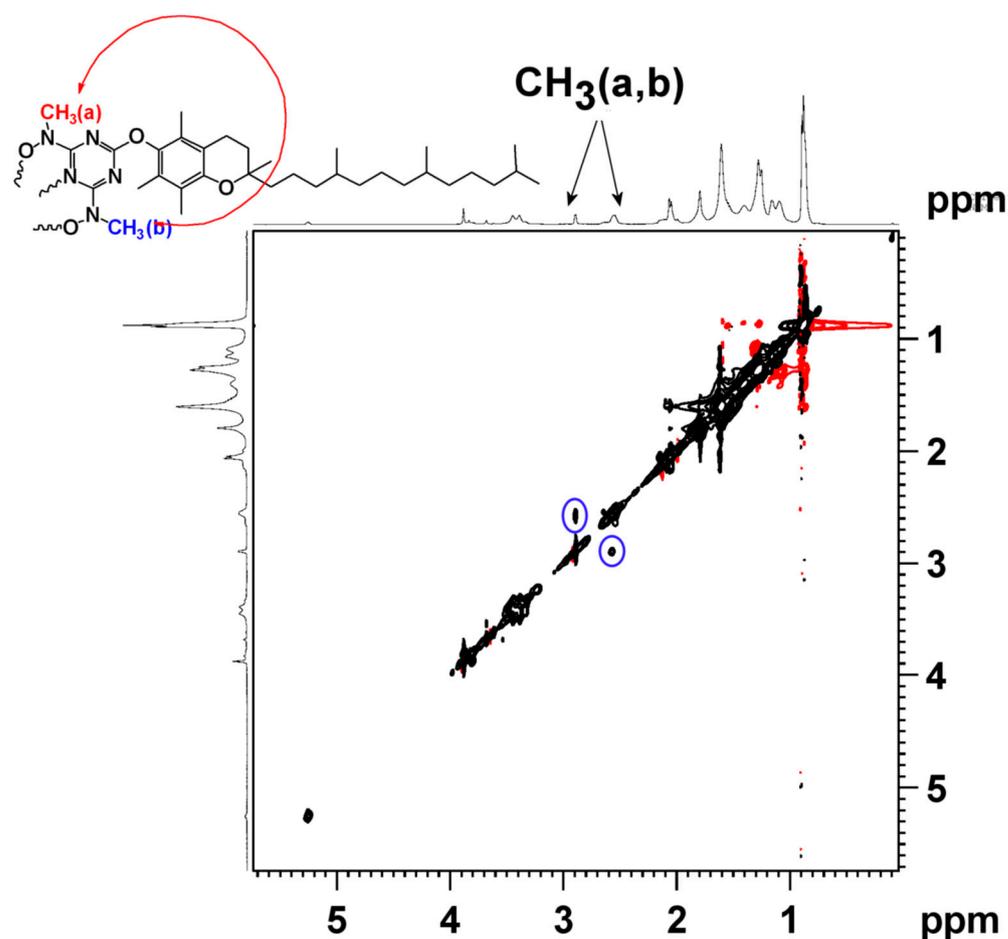

Figure 3. 2D ^1H grNOESY spectrum of CDCl_3 solution of **1** (1.00 mM). Exchange of $\text{CH}_3(\text{a})$ and $\text{CH}_3(\text{b})$ cross peaks in blue circles.

3.4. Complexes Characterisation by UV-Vis

The UV-vis spectra of the CHCl_3 solutions of **1** and **2** are shown in Figure 4. Both gave strong peaks in the visible region [$\lambda(\epsilon)$ of **1** = 493 nm ($3600 \text{ M}^{-1} \text{ cm}^{-1}$), 682 nm ($1140 \text{ M}^{-1} \text{ cm}^{-1}$), $\lambda(\epsilon)$ of **2** = 484 nm ($2300 \text{ M}^{-1} \text{ cm}^{-1}$), 645 nm ($860 \text{ M}^{-1} \text{ cm}^{-1}$)] assigned to the ligand to metal charge transfer transitions (LMCT). The concentration of the complexes in solutions were 0.500 mM, and according to ^{51}V NMR the species in the solution have the monomeric structure, **1m** and **2m** (Scheme 4). Although $[\text{V}^{\text{V}}\text{O}_2(\text{bihyat})]^-$ has a similar structure with the monomers **1m** and **2m**, it does not exhibit any strong absorption peaks in the visible region. Thus, the strong colour of **1m** and **2m** is due to electron transitions from the chromanol ring to the metal. Chromanol ring can contribute electronically to the metal ion through the resonance of the triazine ring (Scheme 5) [42]. The shift of the UV-vis peaks of **1** to lower energy compared to those of **2** agrees with the higher electron density of α - than δ -tocopherol, supporting our hypothesis regarding the significance of the chromanol role on the LMCT effect.

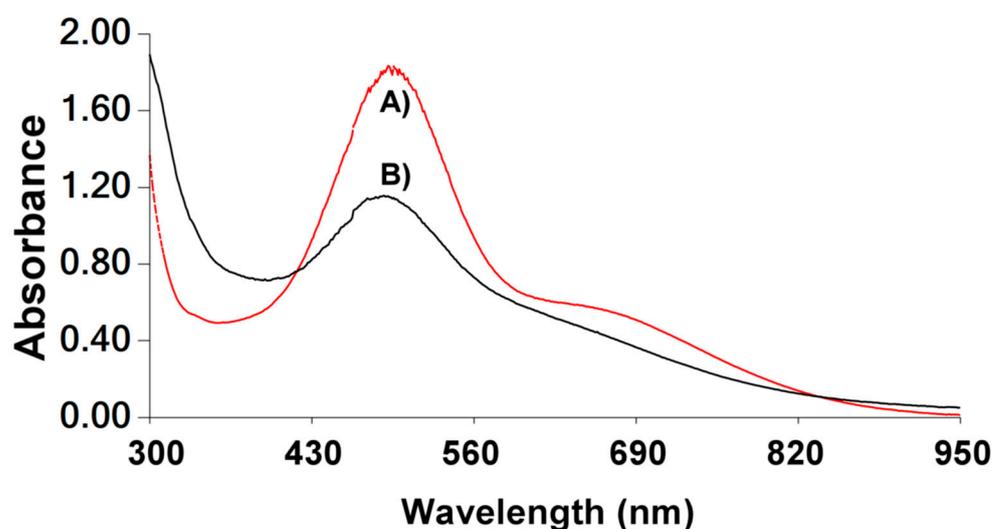

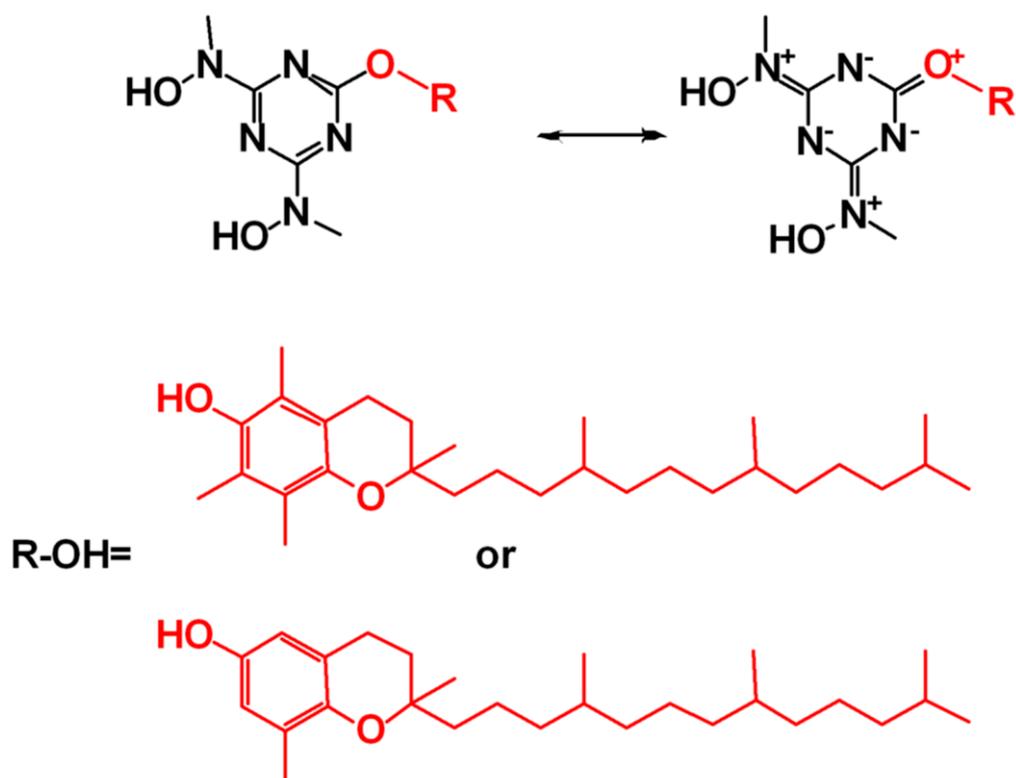

Figure 4. UV-vis spectra of CHCl_3 solutions of 0.500 mM of (A) **1m** [$\lambda(\epsilon) = 493 \text{ nm}$ ($3600 \text{ M}^{-1} \text{ cm}^{-1}$), 682 nm ($1140 \text{ M}^{-1} \text{ cm}^{-1}$)] and (B) **2m** [$\lambda(\epsilon) = 484 \text{ nm}$ ($2300 \text{ M}^{-1} \text{ cm}^{-1}$), 645 nm ($860 \text{ M}^{-1} \text{ cm}^{-1}$)].

Scheme 5. Triazine resonance structures.

The CHCl_3 solutions of Fe^{III} complexes **3** and **4** gave peaks at 560 nm ($3200 \text{ M}^{-1} \text{ cm}^{-1}$) and 535 nm ($2200 \text{ M}^{-1} \text{ cm}^{-1}$) respectively (Figure 5A). These spectra are similar to other hydroxylamine-triazin iron complexes, for example the Fe^{III} -bihyat compounds [41]. Complexes **3** and **4** exhibit the same pattern as the vanadate complexes; the α -tocopherol complex **3** absorbs at lower energy than the δ -tocopherol complex **4**. This is in line with the proposed electron transfer resonance mechanism proposed in Scheme 5.

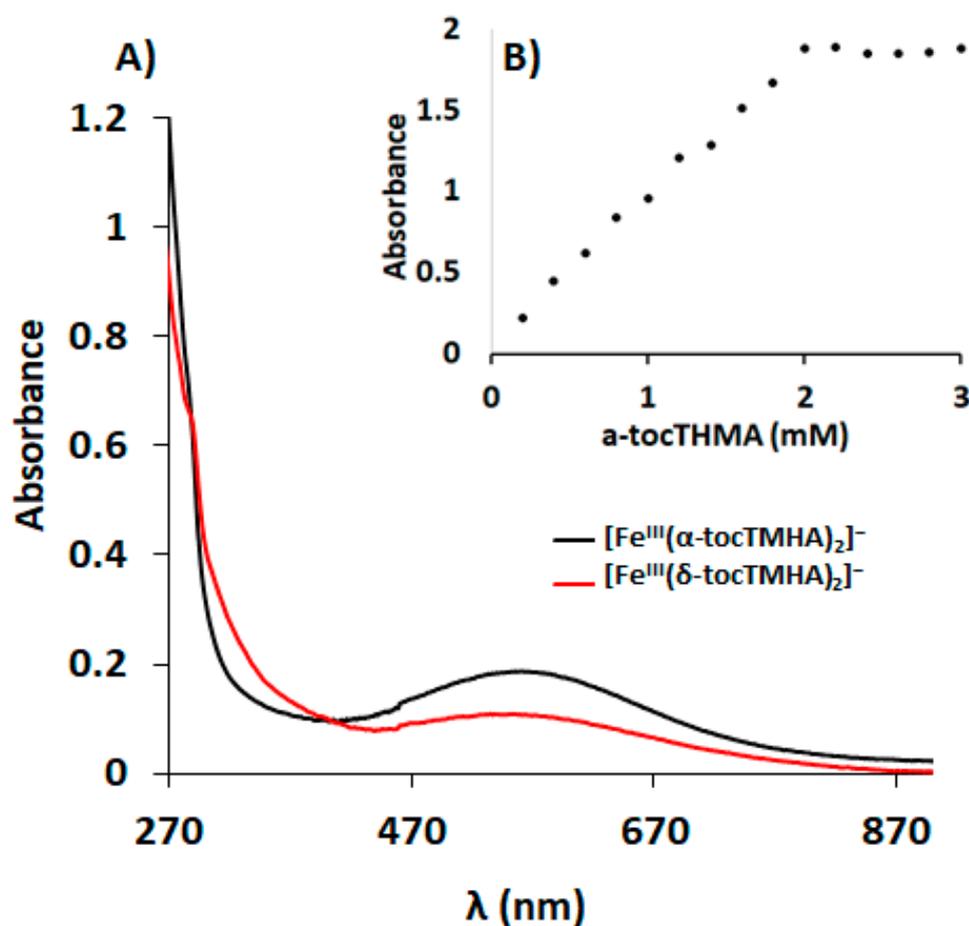

Figure 5. (A) UV-vis spectra of CHCl₃ solutions of 0.100 mM of **3** [black line, $\lambda(\epsilon) = 560$ nm ($3200 \text{ M}^{-1} \text{ cm}^{-1}$)] and **4** [red line, $\lambda(\epsilon) = 535$ nm ($2200 \text{ M}^{-1} \text{ cm}^{-1}$)]. (B) Absorbance at 560 nm vs. the concentration of *a*-tocTMHA added in the CHCl₃ solution of FeCl₃ (1.00 mM).

Addition of various quantities of either H₂α-tocTHMA or H₂δ-tocTHMA to a CHCl₃ solution of Fe^{III}Cl₃ gave the same spectra with **3** and **4** respectively. Titration of the CHCl₃ solution of Fe^{III}Cl₃ with either H₂α-tocTHMA (Figure 5B) or H₂δ-tocTHMA reveal that only the 1:2 Fe^{III}-Ligand complexes are formed in the solution.

3.5. Characterisation of the Complexes in 10% DMSO:90% D₂O Solutions by ⁵¹V NMR

The ⁵¹V NMR spectra of 10% DMSO:90% D₂O solutions of inorganic vanadate with either **1** or **2** at pD = 5.0–7.5 clearly shows very different chemical shifts for the peaks of vanadate oligomers from those of the complexes, undoubtedly assigning the peaks at −560 ppm to the new vanadium complexes (Figures 6 and 7). The addition of D₂O in the DMSO solutions (10% DMSO:90% D₂O, pD = 6.0–7.5) of **1** or **2** at concentrations 0.10 mM do not hydrolyse the complexes as evidenced by the ⁵¹V NMR spectroscopy (the spectra show only one peak originated from the complex and there is no formation of any inorganic vanadate species (Figure 6)). In the ⁵¹V NMR spectra, a shift from −387 ppm in CDCl₃ to −560 ppm in 10% DMSO:90% D₂O observed for **1** originated from the structural change of the complex from tetragonal pyramidal to dioxido octahedral geometry. A similar shift was observed upon changing from CDCl₃ to D₂O solutions for [VO₂(bihyat)]⁻ as well [42]. The 10% DMSO:90% D₂O solutions of **1** or **2** were stable at these conditions for more than 72 h. The high hydrolytic stability of **1** and **2** is attributed to their amphiphilic nature [36,38,39]. The lipophilicity of **1** and **2** may enhance the hydrolytic stabilisation over the non-lipophilic vanadium complexes, exhibiting the same coordination environment, through a more favourable solvation [40].

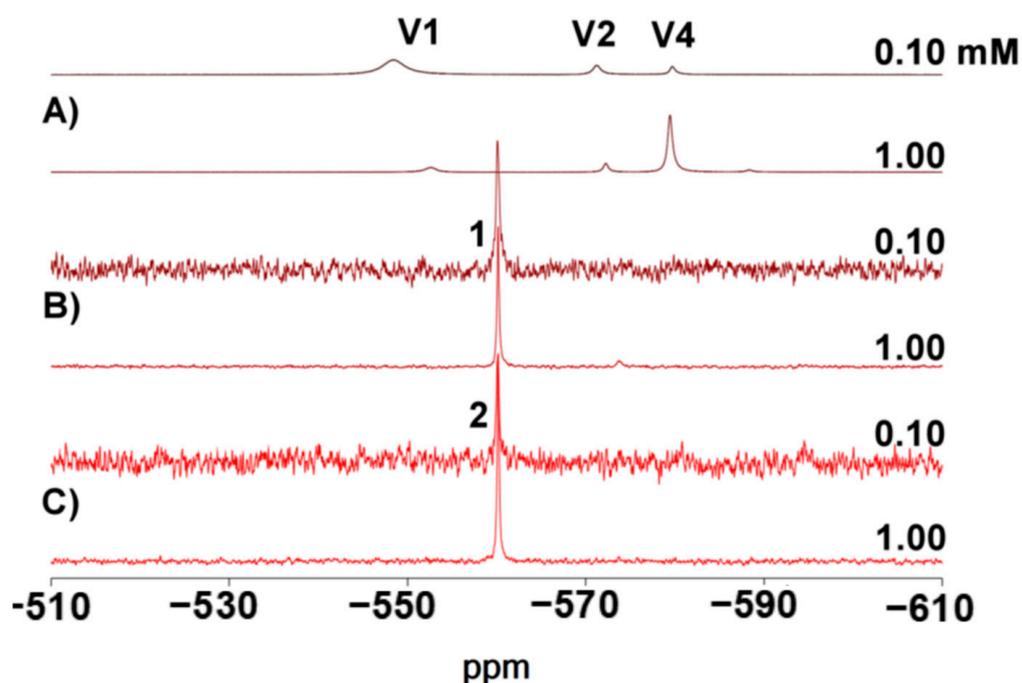

Figure 6. ^{51}V NMR spectra DMSO- d_6 :D $_2$ O (1:9) solutions of (A) NaVO $_3$, (B) **1**, (C) **2** at pD \sim 7. V1, V2, V4 are the vanadium oligomers.

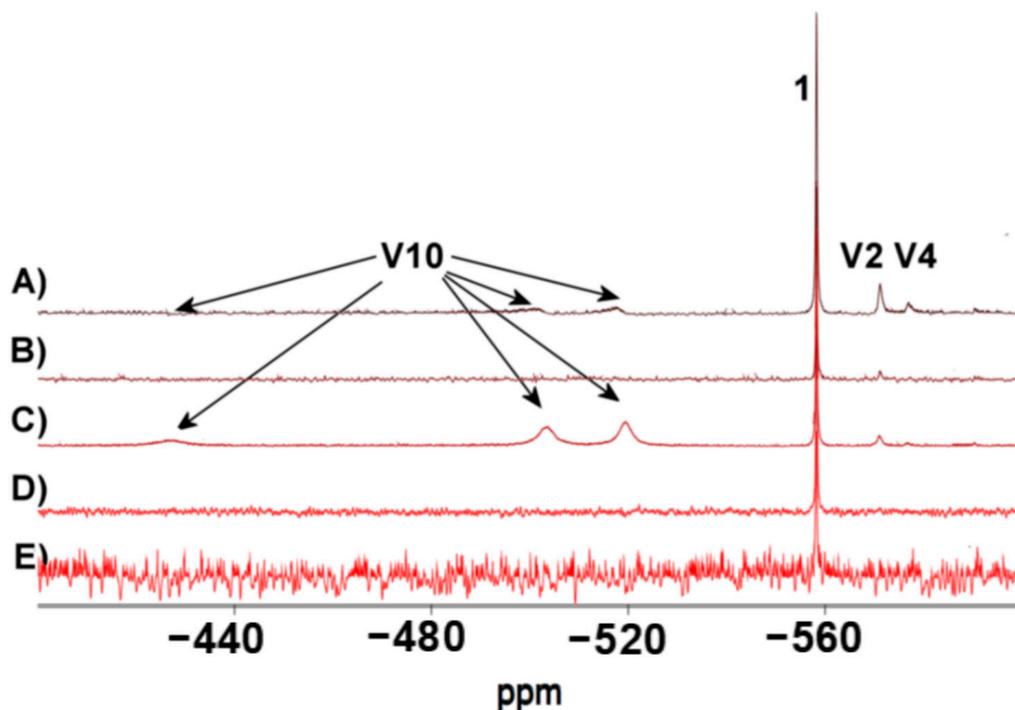

Figure 7. ^{51}V NMR spectra DMSO- d_6 :D $_2$ O (1:9) solutions of (A) 1.00 mM of **1** + 1.00 mM NaVO $_3$, pD = 5.9 (B) 1.00 mM of **1** pD = 5.9 (C) 1.00 mM of **1** + 1.00 mM NaVO $_3$, pD = 5.0 (D) 1.00 mM of **1**, pD = 5.0. (E) 0.10 mM of **1**, pD = 7.0. V10, V2, V4 are the vanadium oligomers.

3.6. Characterisation of the Complexes in 10% DMSO:90% D $_2$ O Solutions by UV-Vis Spectroscopy

The UV-vis spectra of the 10%DMSO: 90%D $_2$ O solutions of **1** and **2** were similar to the spectra of the complexes in CHCl $_3$ (Figure 8). The only difference between the spectra in the two different solvents is the lower intensity of the peaks in 10%DMSO: 90%D $_2$ O than CHCl $_3$. However, complexes **1** and **2** show significant different absorption coefficients

compared to those of $[\text{VO}_2(\text{bihyat})]^-$ in various solvents [42]. The extinction coefficients of **1** and **2** are lower in protic polar solvents than in the non-polar ones in the same manner as $[\text{VO}_2(\text{bihyat})]^-$. The absorbance values from the UV spectra of **1**, **2** solutions appear to obey Beer's law, even at low concentrations at 50 μM , suggesting that the complexes are hydrolytically stable in those solutions (Figure 9), in agreement with ^{51}V NMR spectroscopy. The spectra of the 10% DMSO:90% D_2O solutions of the iron complexes **3** and **4** are also similar with their spectra in CHCl_3 solutions.

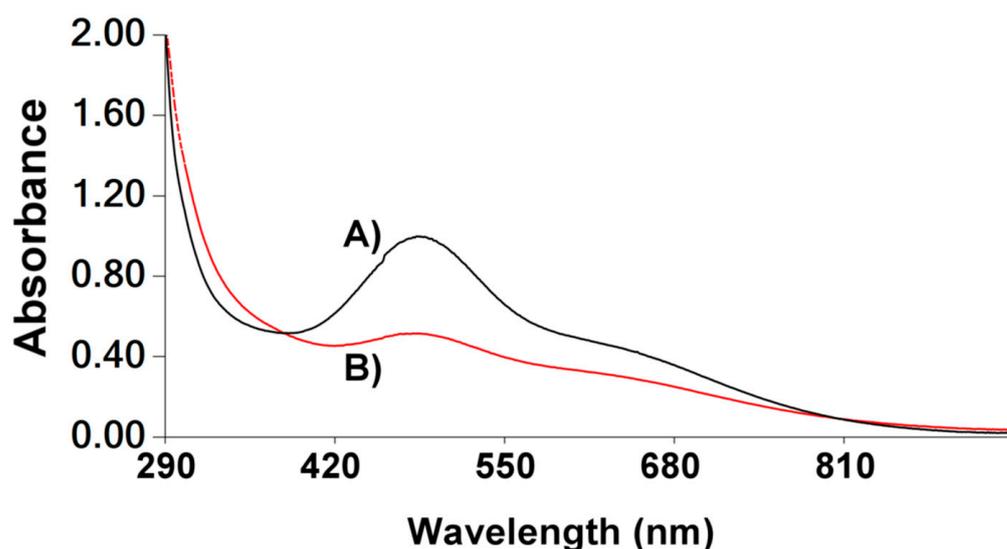

Figure 8. UV-vis spectra of $\text{DMSO-}d_6\text{:D}_2\text{O}$ (1:9) solutions of 0.500 mM of (A) **1** [$\lambda(\epsilon) = 490 \text{ nm}$ ($2000 \text{ M}^{-1}\text{cm}^{-1}$), 675 nm ($900 \text{ M}^{-1}\text{cm}^{-1}$)] and (B) **2** [$\lambda(\epsilon) = 490 \text{ nm}$ ($1100 \text{ M}^{-1}\text{cm}^{-1}$), 675 nm ($660 \text{ M}^{-1}\text{cm}^{-1}$)].

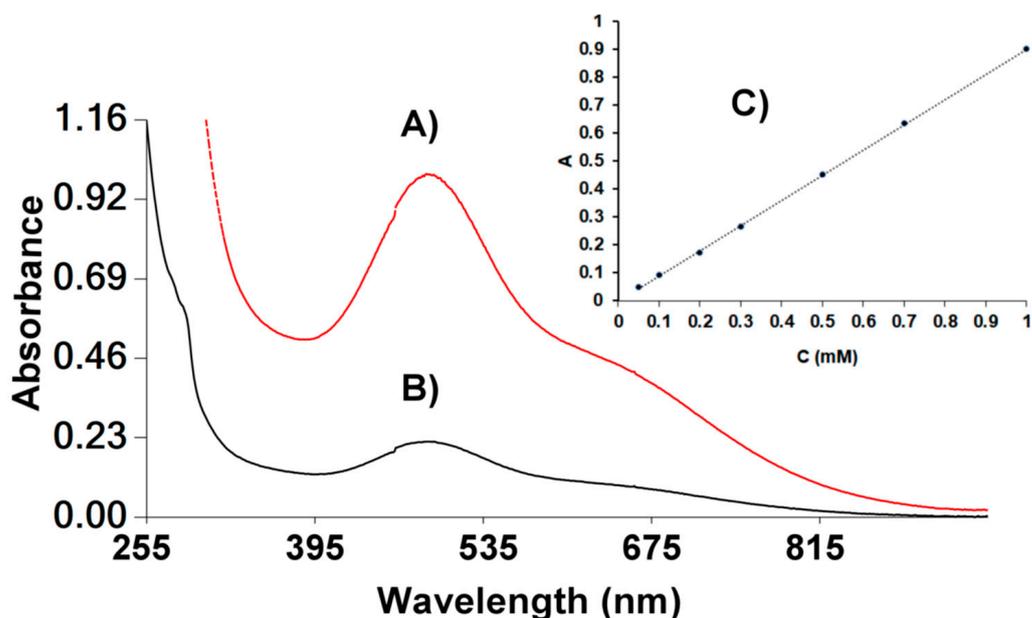

Figure 9. UV-vis spectra of $\text{DMSO-}d_6\text{:D}_2\text{O}$ (1:9) solutions of **1** (A) 0.500 mM and (B) 0.100 mM, (C) graph of the absorption at 490 nm vs. concentration.

3.7. Reactivity with DPPH•

The radical scavenging activity (RSC) values of the organic compounds and the complexes towards scavenging the DPPH• radical are shown in Table 1. α -tocTHMA and δ -tocTHMA exhibit very low antioxidant activity, much lower than free α -tocopherol. The

reason for this low activity is the replacement of the labile phenoxy proton of α -tocopherol with an inert ether bond of α -tocTHMA and δ -tocTHMA. Large number of vanadium complexes exhibit radical scavenging activity [50]. However, complexes 1–4 either did not show any or very little decrease of the peak intensity at 520 nm, resulting in the conclusion that they do not have any antioxidant activity.

Table 1. Rate constants (k_2) for the RSC of the compounds under study.

Compounds	k_2 ($M^{-1}s^{-1}$) Toluene
α -tocTMHA	7.0 ± 0.16
δ -tocTMHA	12.5 ± 0.08
1m	-0.88 ± 0.02
2m	-0.88 ± 0.02
3	5.0 ± 0.09
4	-0.75 ± 0.02
$[V^{IV}O(acac)_2]$	6.8 ± 0.3
α -tocopherol [33]	560 ± 80

3.8. Oxidative Inducing Effect of Vanadium Compounds by EPR Spectroscopy

The ability of the new vanadium compounds to produce radicals was examined by monitoring the generation of α -tocopheryl radicals in olive oil by cw X-band EPR using 2D intensity vs. time experiments (Figure 10). The ability of complexes 1 and 2 were compared with that of the $[V^VO(C18DEA)]$ used in a previous study [36,37]. $[V^VO(C18DEA)]$ has been studied for its activity towards the production of radicals in olive oil, therefore, it is used in this work as a reference. Based on previous studies, it has been reported that V^V and/or V^{IV} coordinated catalytic sites are able to activate phenolics in the lipophilic matrix of oil mediated by dioxygen activation; in this oxidative environment free radicals are trapped by α -tocopherol to give α -tocopheryl radical. The generation of α -tocopheryl radicals is monitored by X-band cw-EPR vs. time. The graph of the signal intensity vs. time is a very useful quantification tool to determine the ability of the complexes to initiate radicals. Experiments were run for two different quantities of each radical initiator for the study, (0.490 μ mole or 0.720 μ mole). The intensity of the EPR peaks, at the same time period after addition of the radical initiator in olive oil is higher for $[V^VO(C18DEA)]$ than 1, meaning that $[V^VO(C18DEA)]$ produces more α -tocopheryl radicals than 1. The intensity of the EPR signal is lower at higher concentrations of the radical initiator due to the faster oxidation of the polar antioxidants that regenerate α -tocopherol in olive oil; the mechanism has been previously investigated [37]. Apparently, $[V^VO(C18DEA)]$, and consequently $[V^VO(\beta$ -tocDEA)] which is stronger initiator than $[V^VO(C18DEA)]$ [36], are by far much more potent radical initiators than 1.

$[V^VO(C18DEA)]$ and $[V^VO(\beta$ -toc)DEA] vanadium complexes have been reported to have high cytotoxicity [36]. If the cytotoxicity of the complexes is related to their oxidative power measured by EPR, then 1 is expected to be less cytotoxic than $[V^VO(C18DEA)]$ or $[V^VO(\beta$ -toc)DEA].

3.9. Cytotoxic Activity

None of the complexes exerted cytotoxic activity against the three cell lines, a fact that differentiated them significantly from the ligands. As seen in Figure 11, exposure of Cal33 cells for 24 h to increasing concentrations of the ligands and the complexes had no severe effect on the ability of the cells to proliferate (Figure 11A,C). Prolongation of the incubation time revealed that complexes 1 and 4 exerted a no-dose-dependent cytotoxicity across the different doses (1 to 100 μ M) leading to a 40% reduction of cell population. On the contrary, the cytotoxic activity of the ligands $H_2\alpha$ -tocTHMA and $H_2\delta$ -tocTHMA as well as the complexes 2 and 3 was depicted mainly at doses higher than 25 μ M. Order of

cytotoxic activity (100 μM) was found as following: $\text{H}_2\delta\text{-tocTHMA} < \text{H}_2\alpha\text{-tocTHMA} < 4 < 1 < 3 < 2$ (24 h), $\text{H}_2\delta\text{-tocTHMA} = \text{H}_2\alpha\text{-tocTHMA} < 2 < 3 < 1 < 4$ (48 h).

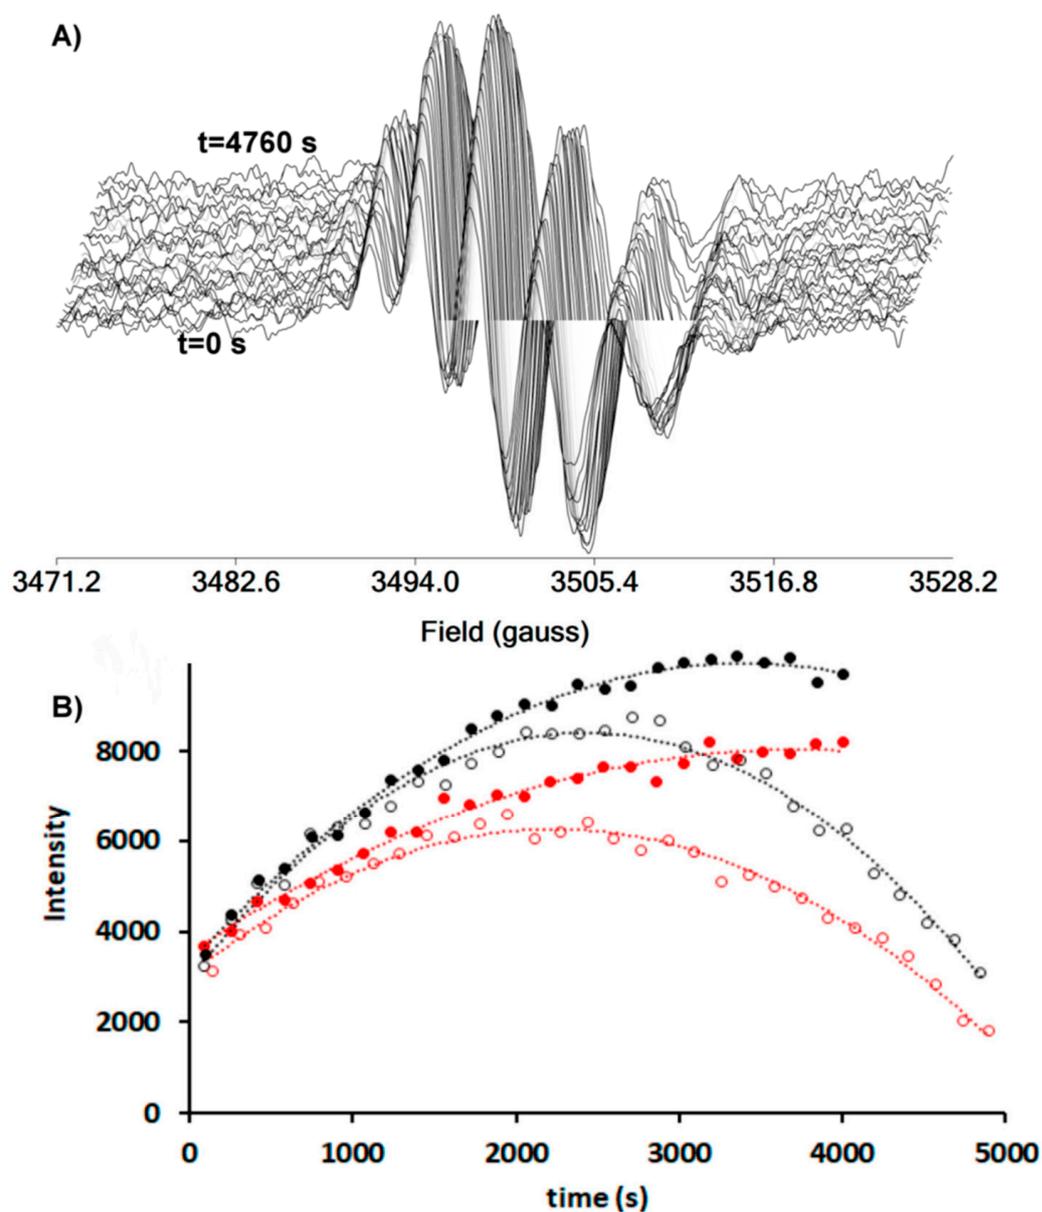

Figure 10. (A) X-band EPR spectra of virgin olive oil (0.500 g) vs. time after addition of **1** (0.720 μmole) at RT. The period between two continues spectra is 150 s. The total number of spectra is 30. (B) Intensity of the α -tocopheryl radical signal in X-band EPR spectra vs. time after the addition of the radical initiator in extra virgin olive oil (0.500 g), $t = 0$ s. Complex **1** (red colour), [VO(C18DEA)] (black colour). Different concentrations of radical initiator with respect to each V^{V} catalytic site per molecule: filled circles (0.490 μmole), open circles (0.720 μmole). The fitting curves have been generated from quadratic equations.

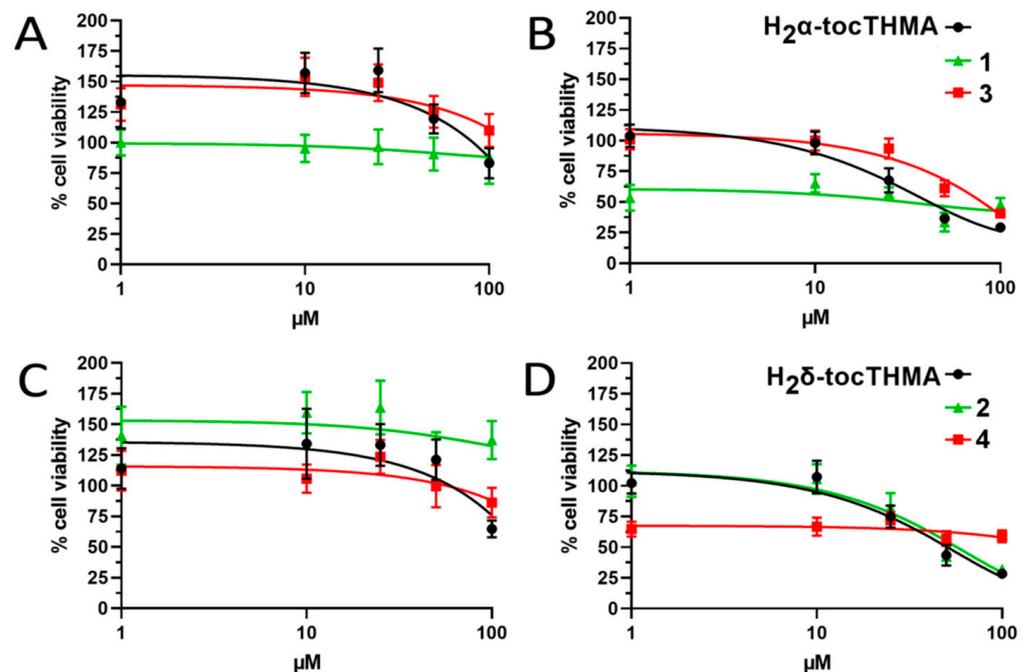

Figure 11. Cytotoxicity of H₂α-tocTHMA (A,B) and H₂δ-tocTHMA (C,D) complexes against Cal33 cells after exposure for 24 (A,C) and 48 h (B,D), respectively.

A similar cytotoxic profile was also seen against HeLa cells (Figure 12). Twenty-four hours of exposure to the ligands and the complexes exerted a mild effect on cell viability even at the highest dose. At 48 h a slightly greater reduction in cell viability was recorded for both ligands and the complexes. Order of cytotoxic activity (100 μM): H₂α-tocTHMA < 3 < 2 < H₂δ-tocTHMA < 1 < 4 (24 h), H₂α-tocTHMA < 1 < 3 = H₂δ-tocTHMA < 2 < 4 (48 h).

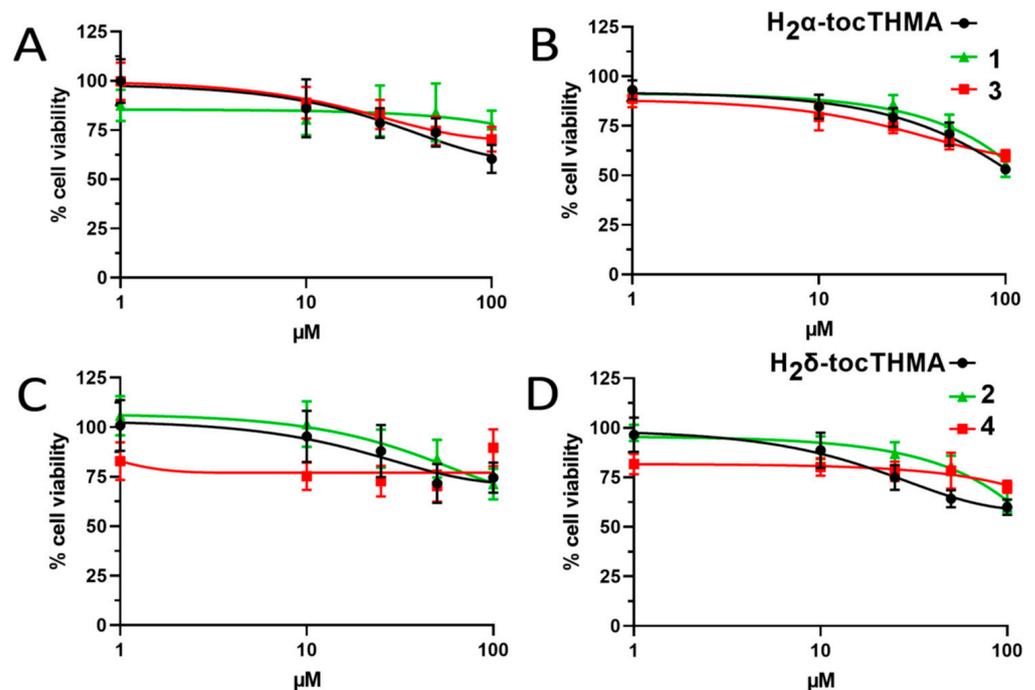

Figure 12. Cytotoxicity of H₂α-tocTHMA (A,B) and H₂δ-tocTHMA (C,D) complexes against HeLa cells after exposure for 24 (A,C) and 48 h (B,D), respectively.

Against embryonic mouse fibroblasts (NIH/3T3), the complexes exerted minimal toxicity after 24 h of incubation (Figure 13A,C). $H_2\alpha$ -tocTHMA presented a strong cytotoxic effect after 48 h, a pattern similar to that seen against Cal33 cells. On the contrary, complexes 1 and 3 had no effect on cell viability and remained relatively non-toxic (Figure 13B). Complex 4 maintains the same cytotoxic profile, as seen in HeLa and Cal33 cells, exerting a mild reduction in cell viability across the range of doses (1–100 μ M) whereas $H_2\delta$ -tocTHMA and 2 were cytotoxic at concentrations higher than 25 μ M (Figure 13D). Order of cytotoxic activity (100 μ M) was found as follows: $2 > H_2\delta$ -tocTHMA $> 1 = H_2\alpha$ -tocTHMA $> 3 > 4$ (24 h), $H_2\delta$ -tocTHMA = $2 > H_2\alpha$ -tocTHMA $> 1 > 4 > 3$ (48 h).

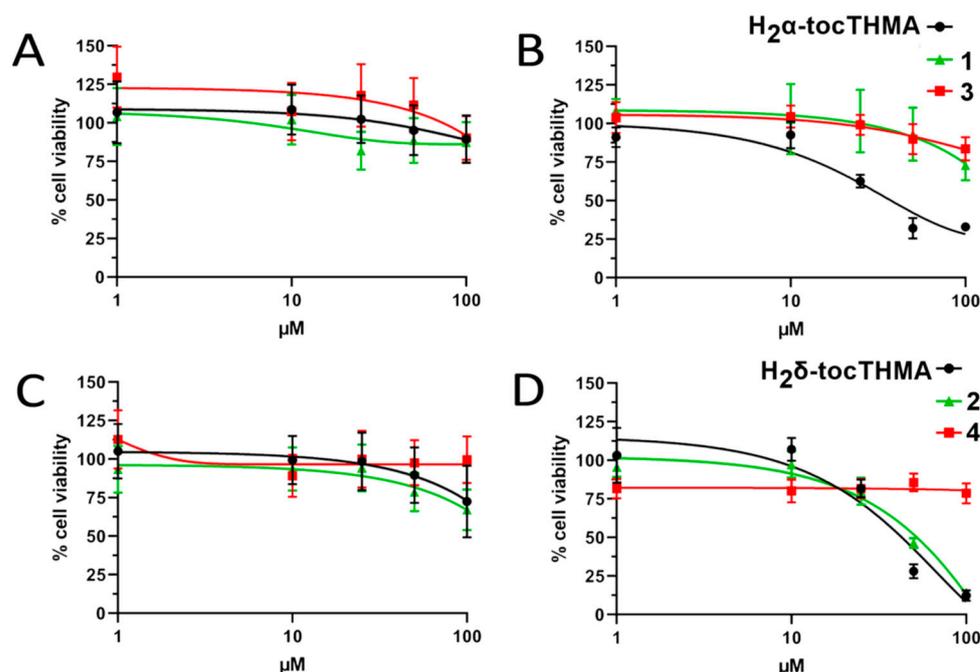

Figure 13. Cytotoxicity of $H_2\alpha$ -tocTHMA (A,B) and $H_2\delta$ -tocTHMA (C,D) complexes against NIH/3T3 cells after exposure for 24 (A,C) and 48 h (B,D), respectively.

4. Conclusions

Stepwise substitution reactions of cyanuric chloride with α - or δ -tocopherol and then with N-methylhydroxylamine resulted in the synthesis of the amphiphilic $H_2\alpha$ -tocTHMA and $H_2\delta$ -tocTHMA ligands. Reaction of the ligands with either the V^{IV} starting materials [$V^{IV}O(acac)_2$] or $V^{IV}OSO_4$ afforded the complexes 1 and 2. Reaction of $Fe^{III}Cl_3$ with $H_2\alpha$ -tocTHMA or $H_2\delta$ -tocTHMA resulted in the formation of complexes 3 and 4 respectively. The new compounds have been characterised by NMR, UV/Vis and infrared spectroscopies. The RSC activities for all compounds have been determined by the DPPH $^\bullet$ assay and the results showed that none of the molecules, ligands or complexes, exhibits antioxidant activity. On the contrary, EPR spectroscopy showed that 1 and 2 are radical initiators. All complexes exhibit high hydrolytic stability even at low concentrations similar to those used in cell viability studies. All complexes, 1–4, do not exerted significant cytotoxic activity against NIH/3T3, Cal33 and HeLa cell lines. The low cytotoxic activity is attributed to the low antioxidant-prooxidant activity of the tocopherol–triazine conjugate molecules. This is in line with the fact that 1 and 2 are moderate radical initiators. Previous studies support that the tocopherol–metal complexes with the hydroxy group of chromanol accessible to metal ion coordination, are stronger radical initiators than 1 and 2, and they exert high cytotoxic activity. However, we cannot exclude the structural differences of the chelate moieties that might induce various biological responses. Currently, the vitamin E metal complexes are rare, and more work is required, including synthesis of new compounds with specific structural features, in order to understand the mechanism of their reactivity.
