## Supplemental Material: A Comparison of the Nephrotoxicity of Low Doses of Cadmium and Lead

Soisungwan Satarug, Glenda C. Gobe, Pailin Ujjin and David A. Vesey

Figure S1. Comparing effects of $E_{c d} / E_{c r}$ and $E_{p b} / E_{c r}$ on eGFR change. The scatterplots relate eGFR to log $\left[(E C d / E c r) \times 10^{3}\right](\mathbf{A})$ and eGFR to $\log \left[(E P b / E c r) \times 10^{3}\right](\mathbf{B})$ in all subjects. The linear equations and coefficients of determination $\left(R^{2}\right)$ are provided together with standardized $\beta$ and $p$-values. The bars represent the mean values for $e G F R$ across $E_{c d} / E_{c r}$ quartiles ( $\mathbf{C}$ ) and $E_{p b} / E_{c r}$ quartiles ( $\mathbf{D}$ ) after adjustment for age, covariates and interactions. The numbers of subjects are provided for all subgroups. The geometric mean (GM) values (standard deviation) for $E_{c d} / E_{c r}$ in quartiles $1,2,3$ and 4 are 0.14 ( 0.06 ), $0.35(0.06), 0.58$ ( 0.09 ) and 1.13 ( 0.51 ) $\mu \mathrm{g} / \mathrm{g}$ creatinine, respectively. The GM (SD) for Epb/Err in quartiles 1, 2, 3 and 4 are 0.49 ( 0.43 ), $1.52(0.14), 2.03$ (0.19) and $3.52(3.56) \mu \mathrm{g} / \mathrm{g}$ creatinine, respectively.

Table S1. Multivariable regression analysis for association of eGFR with $\mathrm{E}_{\mathrm{Cd}} / \mathrm{E}_{\mathrm{cr}}$ and $\mathrm{Epb}_{\mathrm{p}} / \mathrm{E}_{\mathrm{cr}}$.

eGFR is a continuous dependent variable. Independent variables are listed in the first column, including $\mathrm{Ecd}_{\mathrm{cd}} / \mathrm{E}_{\text {cr }}$ as $\log \left[\left(\mathrm{E}_{\mathrm{cd}} / \mathrm{E}_{\mathrm{cr}}\right) \times 10^{3}\right], \mu \mathrm{g} / \mathrm{g}$ creatinine and $\mathrm{Epb} / \mathrm{E}_{\text {cr }}$ as $\log \left[\left(\mathrm{Epb}_{\mathrm{p}} / \mathrm{E}_{\mathrm{cr}}\right) \times 10^{3}\right], \mu \mathrm{g} / \mathrm{g}$ creatinine. A standardized regression coefficient $\beta$ indicates the strength of an association between eGFR and an independent variable. * $p \leq 0.05$ identify statistically significant associations. Adjusted $R^{2}$ value indicates the fraction of eGFR variation explained by independent variables. $+p \leq 0.05$ indicate the model explained a significant variability of eGFR levels.

Table S2. Prevalence odds ratios for reduced eGFR across Ecd/Ecr quartiles and Epb/Ecr quartiles.

| Independent Variables/Factors | eGFR Levels <96 mL/min/1.73 m ${ }^{2}$ |  |  |  |  |

${ }^{\text {a }}$ POR $=$ Prevalence Odds Ratios for eGFR levels $\leq 96 \mathrm{~mL} / \mathrm{min} / 1.73 \mathrm{~m}^{2}$. The eGFR $96 \mathrm{~mL} / \mathrm{min} / 1.73 \mathrm{~m}^{2}$ corresponds to the $25^{\text {th }}$ percentile eGFR. ${ }^{\text {b }}$ Low iron store status is defined as serum ferritin levels $\leq 30 \mu \mathrm{~g} / \mathrm{L}$. ${ }^{*} p \leq 0.05$ indicate a statistically significant increment of POR, compared with the reference. The GM (SD) for $\mathrm{Ecd}_{\mathrm{cd}} / \mathrm{Ecr}_{\mathrm{cr}}$ and $\mathrm{Epb}_{\mathrm{p}} / \mathrm{Ecr}_{\mathrm{cr}}$ together with number of subjects in all urinary Cd quartiles and urinary Pb quartiles are as in Figure S1.
