

Supplementary Materials: Effects of Polydopamine Microspheres Loaded with Silver Nanoparticles on *Lolium multiflorum*: Bigger Size, Less Toxic

Xinrui Wang, Hongyong Luo, Weihua Zheng, Xinling Wang, Haijun Xiao and Zhen Zheng

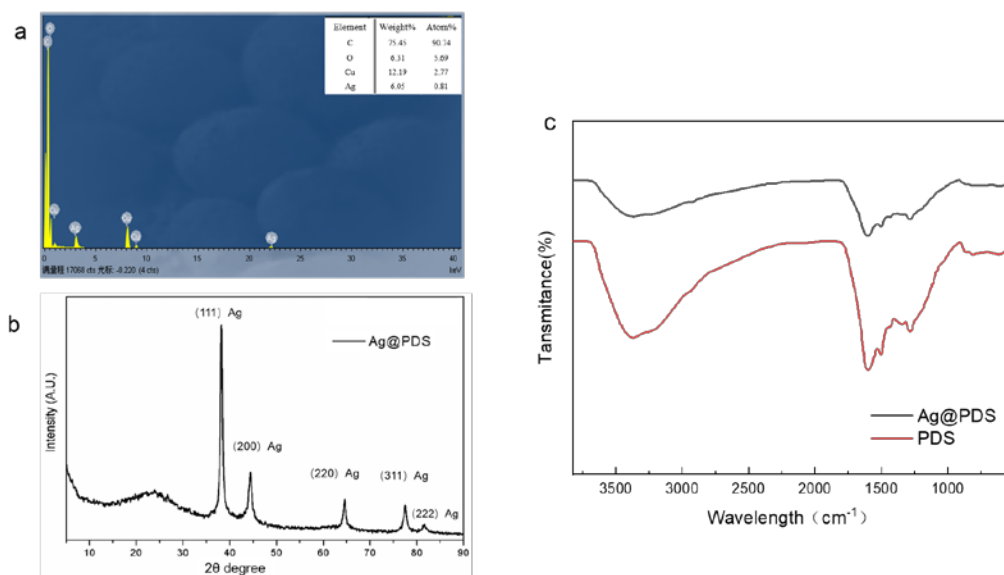

Figure S1. The energy dispersive X-ray spectrum (EDX) confirms well the existence of Ag in Ag@PDS (a). The X-ray diffraction (XRD) patterns of the obtained Ag@PDS (b) evidently reveal that silver ions have been reduced to 0 value of metallic. (c) FT-IR spectra of poly-dopamine spheres (PDS) and poly-dopamine spheres loaded with silver nanoparticles (Ag@PDS).

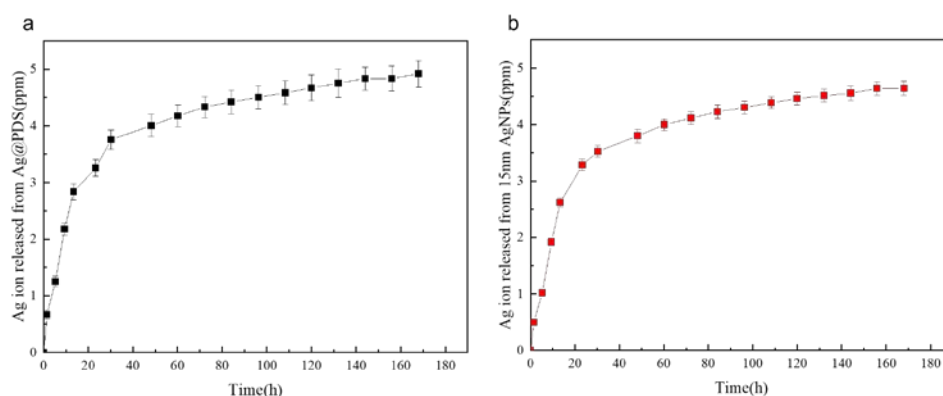

Figure S2. The silver ion released from the Ag@PDS and 15nm AgNPs are merely measurable (< 5ppm) during the observation time with the same Ag concentration.

Figure S3. Root length of *Lolium multiflorum* after several days exposure of 40mg/L of Ag@PDS, AgNO₃ and Ag NPs.

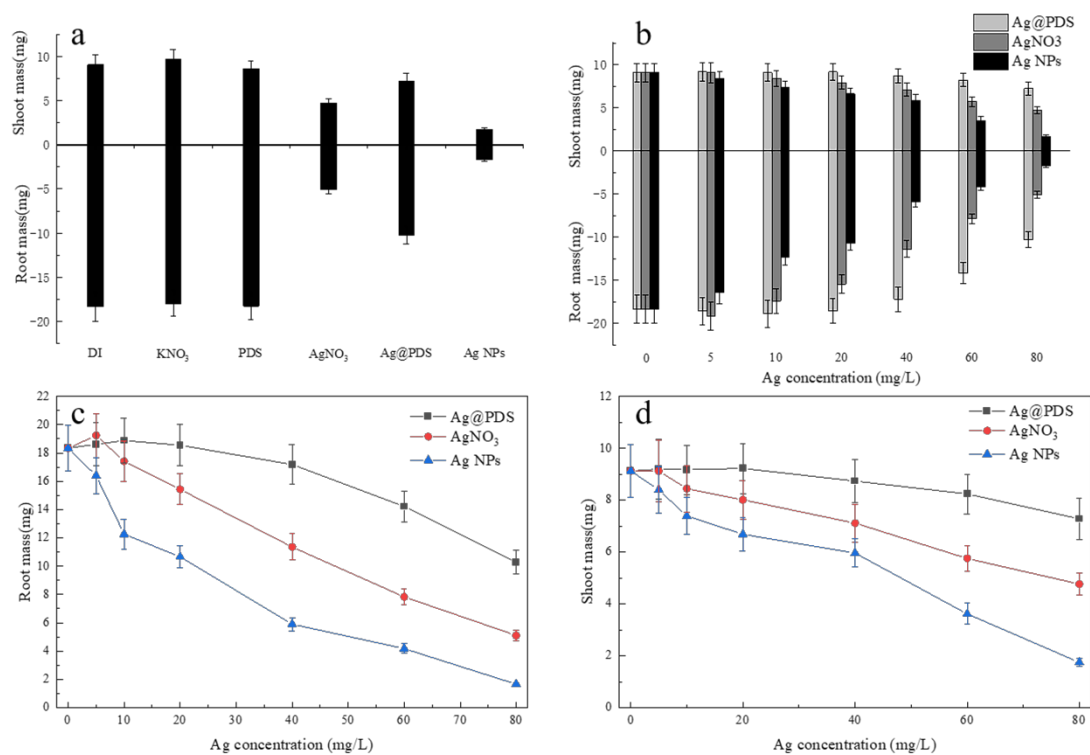

Figure S4. Effect of Ag@PDS, AgNO₃ and AgNPs on the *Lolium multiflorum* root (a, c) and shoot (b, d) mass after 7 days exposure ($p < 0.05$).

Figure S5. TEM images of poly-dopamine spheres loaded with silver nanoparticles (Ag@PDS) with 50 nm scale bar [1].

Figure S6. Images of LB-agar plates which is used in the antibacterial activity experiment of samples against *E.coli*: (a) control, (b) poly-dopamine (PDS), (c) poly-dopamine sphere loaded with silver nanoparticles (Ag@PDS) [1].
