Figure S1. FTIR spectra of drug-free chitosan film (CS-LA), micronized nystatin (NYSm) and NYSm loaded chitosan film (CS-NYSm).

The CS-LA confirms the appearance of electrostatic interactions between protonated chitosan NH_3^+ groups and $-\text{OOCCH}(\text{OH})\text{CH}_3$ carboxylate ions (1737 cm^{-1}). Micronized nystatin shows specific absorption bands for $\text{C}=\text{O}$ stretching vibrations (ester and carboxylic acid groups) and for the $\text{C}=\text{C}$ polyenes units at 1705 cm^{-1} , respectively at 1573 cm^{-1} and 846 cm^{-1} . NYSm dispersion into the CS matrix determine the displacement of the $\text{C}=\text{O}$ characteristic band from 1737 cm^{-1} (CS-LA) to 1733 cm^{-1} (CS-NYSm), also the increase in intensity of band from 1575 cm^{-1} ($\text{C}=\text{C}$ band of NYS superimposed with CS amide/amine bands) [25].
