Abstract: Newborn screening (NBS) programmes are essential in the diagnosis of inherited metabolic diseases (IMDs) and for access to disease modifying treatment. Most European countries follow the World Health Organisation (WHO) criteria to determine which disorders are appropriate for screening at birth; however, these criteria are interpreted and implemented by individual countries differently, creating disparities. Advances in research and diagnostics, together with the promise of new treatments, offer new possibilities to accelerate the expansion of evidence-based screening programmes. A novel and robust algorithm was built to objectively assess and prioritise IMDs for inclusion in NBS programmes. The Wilson and Jungner classic screening principles were used as a foundation to develop individual and measurable criteria. The proposed algorithm is a point-based system structured upon three pillars: condition, screening, and treatment. The algorithm was tested by applying the six IMDs currently approved in the United Kingdom NBS programme. The algorithm generates a weight-based score that could be used as the first step in the complex process of evaluating disorders for inclusion on NBS programmes. By prioritising disorders to be further evaluated, individual countries are able to assess the economic, societal and political aspects of a potential screening programme.

Keywords: newborn screening (NBS); inherited metabolic disease; inherited disorder; public health; paediatrics; rare diseases; genetics; congenital disorders; methodology; Wilson and Jungner

1. Introduction

Newborn screening (NBS) started in the 1960s as a critical part of public health programmes designed to test infants shortly after birth for disorders that can cause disability or death if left undetected and untreated [1]. The goal of NBS is thus to detect disorders before they become symptomatic [2]. While NBS includes a battery of tests, such as newborn hearing, this paper focuses solely on inherited diseases assessed by biochemical NBS carried out by dried blood spot (DBS) testing.

In 1968, the World Health Organisation published a public health paper, “Principles and Practice of Screening for Disease”, that includes ten screening principles of early disease

detection, commonly known as the Wilson and Jungner classic screening principles [3]. Since then, policymakers have been asked to consider an expanding list of disorders for inclusion in their national screening programmes due to advances in treatment options and in diagnostics, such as multiplex testing [4,5]. The Wilson and Jungner classic screening principles are widely used as guidelines for deciding whether a certain disorder is suitable for NBS [4]. However, as many aspects of the classic principles are subjective, disparities across and even within countries have arisen due to differences in the interpretation of the Wilson and Jungner screening principles. Considering Europe as a “geographical area consisting of around 50 countries situated east of the Atlantic Ocean, north of or in the Mediterranean Sea and west of the Ural Mountains, including all of Russia” [5], there are countries that screen newborns for over 20 disorders such as Italy, Hungary or Austria and others that screen newborns for as few as two; such as Armenia, Belarus, or Cyprus, [5]. There is a need for a systematic approach to evaluate disorders for inclusion on NBS programmes.

Our objective was to build an algorithm, based on the Wilson and Jungner classic screening principles, that generates a weight-based score for inherited disorders. The algorithm was designed to be the first step in the complex process of identifying disorders for inclusion on NBS programmes by allowing national authorities to objectively evaluate and prioritise inherited metabolic diseases (IMDs) for inclusion on NBS programmes. If a high score is calculated for a given disorder, it would then need to be evaluated at the local level to assess the economic, societal and political aspects of a potential screening programme. The proposed algorithm could limit the room for interpretation on which IMDs could be added to NBS programmes, reduce the disparity across European countries, and allow for horizon scanning of disorders for future consideration.

2. Materials and Methods

Analysis of the 10 Classic Screening Principles

The Wilson and Jungner classic screening principles were used as the basis of our approach. We organised the ten screening principles into four categories; “Condition”, “Screening”, “Treatment” and “Other” (see Table 1).

Table 1. Wilson and Jungner classic screening principles organised into four key categories.

Wilson and Jungner Classic Screening Principles [3]		Category
1	The condition sought should be an important health problem	Condition
2	There should be an accepted treatment for patients with recognised disease	Treatment
3	Facilities for diagnosis and treatment should be available	Other
4	There should be a recognisable latent or early symptomatic stage	Condition
5	There should be a suitable test or examination	Screening
6	The test should be acceptable to the population	Screening
7	The natural history of the condition, including development from latent to declared disease, should be adequately understood	Condition
8	There should be an agreed policy on whom to treat as patients	Other
9	The cost of case-finding (including diagnosis and treatment of patients diagnosed) should be economically balanced in relation to possible expenditures on medical care as a whole	Other
10	Case-finding should be a continual process and not a “once and for all” project	Other

Three of these categories contain principles that are both clinical and measurable: “Condition”, “Screening” and “Treatment”. The fourth category, “Other”, contains screening principles that are related to the economic, societal or political aspects of screening programmes. The principles that fell into the category “Other” were removed from the algorithm as they are neither clinical nor measurable. The emerging Wilson and Jungner criteria were also evaluated; however, these principles also fall into the category of “Other” as they encompass ethical, economic, and societal aspects of screening programmes which are not included in this algorithm [6]. The algorithm is therefore built upon three pillars: Condition, Screening and Treatment, encompassing the Wilson and Jungner screening principles 1, 2, 4–7 (see Table 2). If a disorder is highly-ranked by the algorithm, a country or regional assessment would be required to take into consideration the economic, societal and political aspects of screening programmes such as cost-effectiveness (principle 9), infrastructure (principle 3), patient-finding and treatment policies (principles 8 and 10).

Table 2. Three pillars of novel algorithm.

Pillar	Wilson and Jungner Classic Screening Principles
Pillar 1: Condition	Principle 1: The condition sought should be an important health problem Principle 4: There should be a recognisable latent or early symptomatic stage Principle 7: The natural history of the condition, including development from latent to declared disease, should be adequately understood
Pillar 2: Screening	Principle 5: There should be a suitable test or examination Principle 6: The test should be acceptable to the population
Pillar 3: Treatment	Principle 2: There should be an accepted treatment for patients with recognised disease

3. Results

3.1. Components of Novel Algorithm

With the intention of developing a point-based system, we explored the nuances of the six identified screening principles included in our algorithm, aiming to parse out individual criteria so that each factor could be assessed, and therefore, measured separately. It is worth mentioning that the Wilson and Jungner screening principles were not designed to evaluate disorders and therefore do not contain objective criteria.

The three clinical and measurable pillars, Condition, Screening and Treatment, contain specific categories and criteria that directly measure the important aspects within each pillar. The weighting of the categories and criteria within the three pillars was determined through the testing of certain agreed upon disorders (see Appendix A, Tables A1–A12). The pillars and their respective categories and criteria are discussed in detail below.

3.1.1. Pillar 1: Condition

This pillar considers Wilson and Jungner principles 1, 4, and 7; relating to the severity, onset and frequency of a disorder. Principle 1: “the condition should be an important health problem.” For this principle, we need to define and measure “important”, which relates to both the severity and the frequency of a disorder. Principle 4: “there should be a recognisable latent or early symptomatic stage”. This principle is related to the timing of the onset of the disorder. As the goal of NBS is pre-symptomatic detection, there must be a reasonable period of time in the natural history of the disorder during which symptoms are not present or not urgently demanding attention [3]. This implies that disorders with symptom presentation in the first few weeks of life are not as strongly recommended for NBS because patients would be diagnosed and treated as a result of early recognition and diagnosis [4]. However, one must keep in mind disorders that, despite presenting very early in life, are severely debilitating or fatal and have treatments which

when administered pre-symptomatically provide superior outcomes. An example is maple syrup urine disease (MSUD), which presents with severe symptoms in the first two or three days of life and can cause irreversible brain damage and death if left untreated, but if identified prior to the development of symptoms, patients can achieve normal growth and development [7]. Principle 7 states that “the natural history of the disorder, including development from latent to declared disease, should be adequately understood”. This principle also underscores the importance of understanding and considering any genotype/phenotype correlations. As many IMDs have multiple phenotypes, or multiple forms, the algorithm must assess the severity, age of onset and proportion of patients with each form of the disorder. Therefore, for the pillar *Condition*, there are three categories: severity, onset, and frequency (see Table 3).

Table 3. Components of Pillar 1, Condition.

Parameter.	Description	Score	Interaction
Severity	The disorder only has severe forms	0.5	AND
	There is a rapidly progressing form	0.5	
	The disorder can be fatal by adolescence	1	
Onset	All forms of the disorder are asymptomatic for the first few weeks of life	1	AND
	More than 50% of cases are an early-onset phenotype	1	
Frequency	Greater than or equal to 1 in 50,000	2	OR
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	1.5	
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	1	
	Between 1 in 250,000 and 1 in 150,000	0.5	

Severity: In looking at the severity of a disease, we must consider the progression and fatality for all forms of the disorder. While DBS tests may be able to identify affected individuals, some disorders have a broad spectrum of phenotypes, with both an early-onset, life-threatening form and an attenuated, less severe phenotype [8,9]. The proposed algorithm considers all forms (from mild to severe) of a given disorder and attributes 0.5 points to disorders with only severe forms, 0.5 points to disorders with a rapidly progressing form, and 1 point to disorders that can be fatal from birth to adolescence (see Table 3). These criteria are not exclusive, and a disorder can receive points for all components. For example, phenylketonuria (PKU) fulfils one criterion (see Table A11 in Appendix A), while medium-chain acyl-CoA dehydrogenase deficiency (MCADD) fulfils two (see Table A7 in Appendix A) and glutaric aciduria type 1 (GA1) fulfils all three criteria (see Table A1 in Appendix A).

Onset: Disease onset is one of the more complicated categories because many IMDs have multiple forms with different ages of onset for the different forms. There is agreement that disorders that are both early-onset and severe should be included in NBS, but there is not consensus that disorders that are adult-onset or have attenuated phenotypes should be included in NBS programmes [1]. Diagnosing late-onset disorders through NBS can create “patients in waiting” and could cause anxiety and uncertainty for healthcare practitioners and families in relation to prognosis, management and potential treatment options [1]. The proposed algorithm prioritises disorders where the larger majority of cases are early-onset in order to directly address access to early diagnosis and also take into account “patients in waiting” (see Table 3). To demonstrate how this would be applied we can compare two disorders: carnitine palmitoyltransferase (CPT) II deficiency and homocystinuria (HCU). CPT II has three subtypes: a lethal neonatal form, a severe infantile hepatocardiomyopathy form, and a myopathic form, which is the most common and where affected individuals have a normal life expectancy [10]. In HCU the majority of patients present with signs and symptoms during the first year of life, however there are also patients who do not develop

symptoms until later childhood or adulthood [11]. While both disorders are asymptomatic for the first few weeks of life, the algorithm would prioritise HCU, where the majority of cases are early-onset, over CPT II, where the majority of cases are later-onset. Early-onset is defined per disorder based on the epidemiologic data available in the peer-reviewed literature. Although it is generally agreed that creating “patients in waiting” should be avoided, it is interesting to note that among individuals with later-onset lysosomal storage disorders (LSDs), the value of NBS for their disorder is recognised, as it would have reduced or eliminated their diagnostic odysseys and potentially altered their life planning [12].

Frequency: The algorithm assigns more points to disorders that have a higher frequency because NBS would allow for increased patient-finding. As disease frequency data is not always available, the algorithm considers either incidence or prevalence. There are four thresholds for frequency from ultra-rare (between 1 in 250,000 and 1 in 150,000) to more common (greater than or equal to 1 in 50,000; see Table 3). The highest-ranking threshold, for the more frequent disorders, includes disorders that are significantly less common as compared to those of the European Commission and the International Society for Pharmacoeconomics and Outcomes Research’s definition of “rare disease” [13].

3.1.2. Pillar 2: Screening

This pillar considers Wilson and Jungner principles 5 and 6 relating to the availability and performance of diagnostic assays. Principle 5 states that “there should be a suitable test or examination”. According to Principle 6, “the test should be acceptable to the population”.

Availability: Since the 1970s, DBS have been routinely used in NBS because only a small volume of blood is required, and the sample is easily collected and transported on filter paper [13]. Tandem mass spectrometry (MS/MS) and liquid chromatography-tandem mass spectrometry (LC-MS/MS) have drastically advanced screening capabilities because one DBS can be analysed for an increasing number of metabolic disorders, allowing for the expansion of NBS programmes [5,14].

Performance: While the acceptability of a DBS test is generally accepted, the suitability of a test is subject to interpretation. We have defined this as the capacity of the DBS test to correctly identify patients with or without the disorder, or to put it another way, to have false positive and false negative rates that are acceptable for a screening test. Indeed, false-negative results allow true disease to go undetected, while false-positive results can induce a stressful situation and anxiety for families while waiting for confirmatory tests to be performed. Moreover, high false-positive rates result in a multiplication of confirmatory tests that can affect the cost-effectiveness of screening. There is not an agreed upon sensitivity, specificity, positive predictive value (PPV), or negative predictive value for screening tests in general [15]. In newborn screening, there can be additional complicating factors, such as the need to define referral rules based on levels of enzyme activity reported in the screening test [16].

The proposed algorithm recognises both the performance of the assay and its suitability as a screening test. Disorders which have a validated DBS assay with a lower false-positive rate are prioritised over disorders where a DBS test is in development, or a DBS test has a low performance. Additionally, if the DBS test has a high-false positive rate, low PPV, or if a tiered-screening strategy is required, the additional confirmatory strategy must be readily available to be integrated into the screening process (see Table 4). As an example, in mucopolysaccharidoses type I (MPS I), a two-tier screening process is in place, with confirmatory genetic testing carried out for newborns with abnormal alpha-l-iduronidase (IDUA) levels on a multiplex assay [17].

Table 4. Components of Pillar 2, Screening.

Parameter	Description	Score	Interaction
Availability	DBS test is available and in use	2	OR
	DBS test is not yet available, but is in development with published evidence	1	
Performance	DBS test has a low false-positive rate and/or a high positive predictive value (PPV)	1	OR
	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance	0.5	

3.1.3. Pillar 3: Treatment

This pillar considers Wilson and Jungner’s principle 2: “there should be an accepted treatment for patients with recognised disease.” Considering this principle and the need to add more granularity, we have created two categories for treatment: availability and outcomes.

Availability: Looking at treatment availability, the proposed algorithm ranks European Medicines Agency (EMA) approved treatments the highest, followed by other treatment interventions (such as diet, bone marrow transplant (BMT) or hematopoietic stem cell transplantation (HSCT)) or treatments in phase III clinical development (see Table 5). Treatments with EMA-approval have gone through rigorous clinical development programmes and received marketing authorisation (MA) for a specific indication [18]. Other treatment interventions, such as diet or HSCT, are less likely to have the same amount of published evidence or randomised controlled trials. The algorithm was designed to be agile and forward-looking; therefore, treatments in development are included to ensure that all available evidence is evaluated. Treatments in phase III clinical trials are assigned more points as compared with those in phase I/II clinical trials as they are more advanced in their likelihood to reach MA. The algorithm only considers one treatment strategy per disorder; the “most-advanced” treatment strategy, meaning that if there is an EMA-approved treatment available, there are no extra points given for other treatment interventions, or treatments in clinical development.

Table 5. Components of Pillar 3, Treatment.

Parameter	Description	Score	Interaction
Availability	An EMA-approved treatment is available	1.5	AND
	A treatment intervention is available (diet, HSCT, BMT)	1	
	A treatment is in late development (phase 3)	1	
	A treatment is in early development (preclinical, phase 1, or phase 2)	0.5	
Outcomes	The treatment strategy changes the prognosis for all forms of the disorder	1.5	OR
	The treatment strategy changes the prognosis for some forms of the disorder	1	
	The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0.5	
	Pre-symptomatic initiation results in better outcomes	1	AND

Outcomes: In addition to treatment availability, we must also evaluate patient outcomes. In the Treatment Outcomes category, the term “treatment strategy” includes EMA-approved treatments, treatments in development and treatment interventions, such as HSCT or BMT. In this category, treatment strategies that impact prognosis receive more

points than those that only manage symptoms. Finally, disorders with a treatment strategy that can provide superior patient outcomes if initiated pre-symptomatically are strongly recommended independently of all other criteria (see Table 5).

3.2. Weighting of Novel Algorithm

After all of the critical components were accounted for, we adjusted the relative weights, aiming to balance globally and within each pillar through the testing of certain disorders. A disorder can score a maximum of 13 points, six for *Condition*, three for *Screening* and four for *Treatment* (see Figure 1). *Condition* includes both the natural history and the frequency of a disorder, but with the natural history counting for twice as much, four points, as frequency which is only two points.

Condition (score range [0–6])			Screening (score range [0–3])			Treatment (score range [0–4])			
Severity	The disorder only has severe forms	0.5	Availability	DBS test is available and in use	2	Availability	An EMA-approved treatment is available	1.5	OR
	There is a rapidly progressing form	0.5		DBS test is not yet available, but is in development with published evidence	1		A treatment intervention is available (diet, HSCT, BMT)	1	
	The disorder can be fatal by adolescence	1	Performance	DBS test has a low false-positive rate and/or a high PPV	1		A treatment is in late development (phase 3)	1	
Onset	All forms of the disorder are asymptomatic for the first few weeks of life	1		OR	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance		0.5	A treatment is in early development (preclinical, phase 1, or phase 2)	
	More than 50% of cases are an early-onset phenotype	1	Outcomes					The treatment strategy changes the prognosis for all forms of the disorder	
Frequency	Greater than or equal to 1 in 50,000	2		OR	The treatment strategy changes the prognosis for some forms of the disorder		1		
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	1.5			The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0.5			
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	1			Pre-symptomatic initiation results in better outcomes	1	AND		
	Between 1 in 250,000 and 1 in 150,000	0.5							

Figure 1. NBS evaluation algorithm.

As in the Wilson and Jungner classic screening principles, the pillar *Condition* is the most comprehensive and therefore contributes to nearly half, 46%, of the total score in the algorithm (see Figure 2). The pillar *Treatment* contributes 31% of the total score, while the more straightforward pillar *Screening* contributes to 23% of the total score. The proposed algorithm prioritises severity of the disorder (23%) and treatment outcomes (20%), with other criteria contributing as follows to the total score: frequency of disorder (16%), availability of diagnostic test (15%), treatment availability (11%), performance of diagnostic test (8%) and onset of disorder (7%) (see Figure 2).

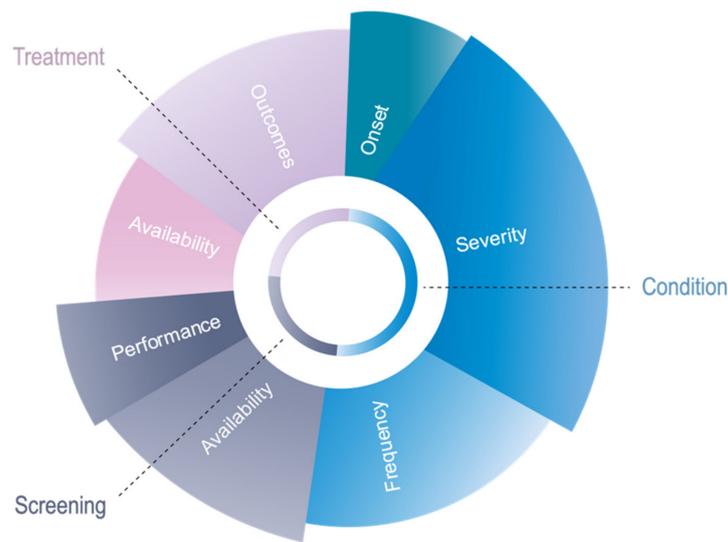

Figure 2. Components of novel algorithm.

3.3. Validation of Novel Algorithm

The algorithm was validated by applying the current IMDs that are on the UK NBS programme, assuming that these would be highly ranked by our algorithm. These disorders: GA1, HCU, isovaleric acidaemia (IVA), MCADD, MSUD and PKU are assessed individually with results shown in Figure 3 (detailed scoring in Appendix A, Tables 4, A1–A3 and A5–A12). Using the algorithm, these six disorders all scored above 8.5 points, therefore we propose that a disorder scoring ≥ 8.5 could be recommended for consideration for NBS programs after taking the economical and societal aspects into account.

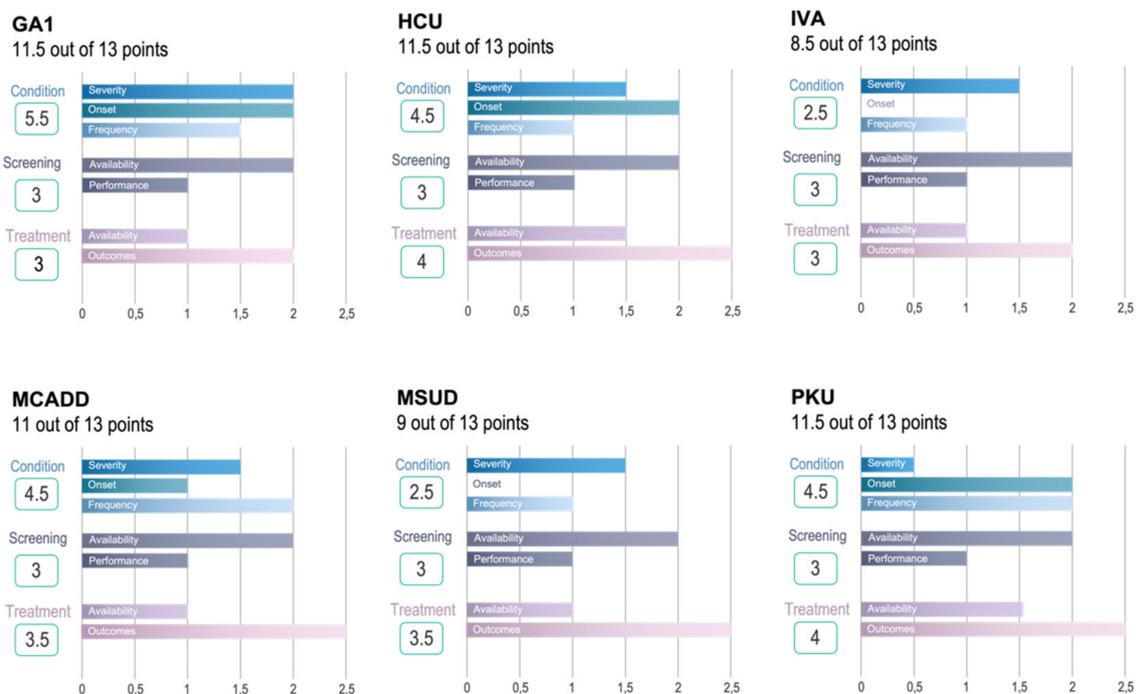

Figure 3. Total scores for the six IMDs on the UK newborn screening panel.

4. Discussion

The proposed algorithm would provide an objective evaluation of the available evidence and generate a score to prioritise disorders for inclusion on NBS programmes. The algorithm does not include a cost effectiveness analysis, but instead facilitates the identification of disorders that would then need to be assessed in a health economics analysis phase. The algorithm was designed to include specific, individual criteria that could be used and applied to horizon scanning for future expansion of a NBS panel or when new information becomes available. For example, when a treatment receives EMA-approval, a disorder can be easily re-tested, and a new score can be determined. The algorithm is also flexible in its application and can be used to evaluate other inherited disorders. In this paper it has been applied to IMDs; however, it could be applied specifically to lysosomal storage disorders or to other inherited disorders as per specific country needs. Similarly, the algorithm could consider other major health and regulatory authorities, such as the Food and Drug Administration or the Medicines and Healthcare products Regulatory Agency in lieu of the EMA.

While the algorithm was designed to be comprehensive, there are inherent limitations due to the complicated nature of inherited disorders. One limitation is that the algorithm only considers the highest scoring treatment per disorder. While this allows for an objective measure of the highest standard of care, disorders with multiple treatment options do not receive extra points. Secondly, as there are no guarantees for drug approval or successful outcomes of clinical trials, there is an inherent risk in horizon scanning for promising treatments. However, the algorithm assigns equal points to treatments in phase three development and treatment strategies because of the inherent complexities of completing robust phase three clinical trials in the rare disease space and the importance of this work. Lastly, while the algorithm aims to eliminate the subjectivity of NBS, there will always be ethical questions to consider. As an example, it is hard to imagine that there could be “an agreed policy on whom to treat as patients” as called for in the Wilson and Jungner principles. The algorithm was designed to prioritise disorders where most patients have an early-onset form; however, we must be aware that this also affects disorders where most patients have a later-onset form. For these disorders with a risk of late-onset, it is important to ensure that with NBS there are procedures in place to counsel families. The proposed algorithm attempts to balance the risk of creating patients-in-waiting for later-onset forms with the benefit of NBS for early-onset forms with rapid disease progression and a small treatment window.

Despite the rich discourse on how to come together across the EU and harmonise NBS programmes [5,19,20], there has been little forward motion. This algorithm attempts to provide a concrete tool for the progress that is so desired. The French National Authority for Health (Haute Autorité de Santé—HAS) has published their independent health technology assessment in 2020. The HAS developed an original method to prioritise diseases to be included in the existing neonatal blood screening program through a process of multi-criteria decision analysis (MCDA) using a number of criteria that are weighed by a limited number of stakeholders (physicians, labs performing the tests, patient groups and ethical experts). Specific diseases under assessment are subsequently scored on each of these criteria and ranked (article under review). This expertise allowed a recommendation to extend NBS by MS/MS to seven inborn errors of metabolism from the 24 studied (HCU, IVA, MSUD, TYR, GA1, Long-chain 3-hydroxyacyl-CoA dehydrogenase [LCHAD], and carnitine uptake defect/carnitine transport defect [CUD]). They will be implemented in the French NBS programme in addition to the two inborn errors of metabolism already screened [21]. This approach is a noteworthy model on how a horizon scanning tool, such as our proposed algorithm, could facilitate prioritization and expansion of NBS at a national level. In the United States we also see a model for evidence-based recommendations combined with regional implementation. The Recommended Uniform Screening Panel (RUSP) lists disorders which have passed scientific review and are recommended for

universal screening; however, it is up to the individual states to decide which disorders will be screened for [22].

Expanded NBS programmes benefit patients, society, and the healthcare system. NBS programmes add to the current body of knowledge on the natural history of disorders because screening increases patient findings, and with more information on genotype/phenotype correlations, disease progression and treatment outcomes, further advances can be made. Our goal is for this algorithm to pave the way forward for evidence-based expansion of NBS programmes by allowing countries to objectively evaluate disorders while maintaining the ability to separately evaluate specific economic, societal, and political aspects of their own screening programmes.

Informed Consent Statement: Not applicable.

Acknowledgments: ArchAngel MLD Trust for the inception of this work, Charlotte Chanson and Annamarie Dillon of Orchard Therapeutics for their support in coordinating and supporting the expert group during the whole project.

Conflicts of Interest: The authors declare no conflict of interest. Orchard Therapeutics had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, or in the decision to publish the results.

Appendix A. Detailed Scoring for the Six IMDs on the UK Newborn Screening Panel are Shown in the Following Tables

Table A1. Glutaric aciduria type 1 (GA1), 11.5 points.

Condition (5.5 out of 6 Points)		Screening (3 out of 3 Points)		Treatment (3 out of 4 Points)						
Severity	The disorder only has severe forms	0.5	AND	Availability	DBS test is available and in use	2	OR	An EMA-approved treatment is available	0	
	There is a rapidly progressing form	0.5			DBS test is not yet available, but is in development with published evidence	0		A treatment intervention is available (diet, HSCT, BMT)	1	
	The disorder can be fatal by adolescence	1			DBS test has a low false-positive rate and/or a high PPV	1		A treatment is in late development (phase 3)	0	OR
Onset	All forms of the disorder are asymptomatic for the first few weeks of life	1	AND	Performance	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance	0	OR	A treatment is in early development (preclinical, phase 1, or phase 2)	0	
								More than 50% of cases are an early-onset phenotype	1	The treatment strategy changes the prognosis for all forms of the disorder
Frequency	Greater than or equal to 1 in 50,000	0	OR					The treatment strategy changes the prognosis for some forms of the disorder	1	OR
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	1.5						The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0	
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	0						AND	Pre-symptomatic initiation results in better outcomes	1
	Between 1 in 250,000 and 1 in 150,000	0								

Table A2. GA1 Scoring.

	Condition	Screening	Treatment
Severity	<p>There is a rapidly progressing form The condition only has severe forms The condition can be fatal by adolescence</p> <p>- If not promptly and properly treated, GA1 will typically cause serious, irreversible neurologic damage that can permanently affect control of voluntary muscle movement and can severely impact life and shorten life expectancy, especially if damage occurs before the age of six. (Rarediseases.org)</p> <p>- The low excreting patients have the same risk of developing striatal injury as the high excretors and must not be considered to have a “mild” clinical phenotype. [23]</p>	<p>DBS test is available and in use</p>	<p>A therapeutic strategy is available (diet, HSCT, BMT) Treatment consists of a low lysine diet and oral carnitine supplementation as well as intermittent emergency treatment during episodes that are likely to induce catabolism. (Rarediseases.org)</p>
Onset	<p>All forms of the condition are asymptomatic for the first few weeks of life More than 50% of cases are an early-onset phenotype Neonates are mainly asymptomatic, with onset usually between three months and three years. (Rarediseases.org)</p>	<p>DBS test has a low false-positive rate or a high PPV [23] Note on sensitivity: Patients with the low excreting phenotype may be missed by newborn screening. (Rarediseases.org; [23])</p>	<p>The therapeutic strategy changes the prognosis only for some forms of the condition Pre-symptomatic initiation results in better outcomes For 80–90% of people with GA1, motor symptom development is preventable, but this requires early diagnosis by newborn screening and treatment from birth on. (Rarediseases.org)</p>
Frequency	<p>Incidence/prevalence is $\geq 1/100,000$ and $< 1/50,000$ Birth incidence is 1/100,000 [24]</p>		

Table A3. Homocystinuria (HCU), 11.5 points.

Condition (4.5 out of 6 Points)		Screening (3 out of 3 Points)		Treatment (4 out of 4 Points)						
Severity	The disorder only has severe forms	0	Availability	DBS test is available and in use	2	Availability	An EMA-approved treatment is available	1.5		
	There is a rapidly progressing form	0.5		AND	DBS test is not yet available, but is in development with published evidence		0	OR	A treatment intervention is available (diet, HSCT, BMT)	0
	The disorder can be fatal by adolescence	1		AND	DBS test has a low false-positive rate and/or a high PPV		1	OR	A treatment is in late development (phase 3)	0
Onset	All forms of the disorder are asymptomatic for the first few weeks of life	1	Performance	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance	0	Performance	A treatment is in early development (preclinical, phase 1, or phase 2)	0		
	More than 50% of cases are an early-onset phenotype	1		AND				OR	The treatment strategy changes the prognosis for all forms of the disorder	1.5
Frequency	Greater than or equal to 1 in 50,000	0	Frequency			Outcomes	The treatment strategy changes the prognosis for some forms of the disorder	0		
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	0		OR				OR	The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	1						AND	Pre-symptomatic initiation results in better outcomes	1
	Between 1 in 250,000 and 1 in 150,000	0								

Table A4. HCU Scoring.

	Condition	Screening	Treatment
Severity	<p>There is a rapidly progressing form of the condition that can be fatal by adolescence Infants with untreated HCU will slowly develop the various symptoms associated with the disorder. The major cause of early death are blood clots, especially in untreated patients. (Rarediseases.org)</p>	<p>DBS test is available and in use</p>	<p>An EMA-approved therapy is available Betaine anhydrous is a methyl donor that may lead to lowering of homocysteine levels in these individuals and can be used as an adjunct to such a diet. It obtained EU marketing authorization as an orphan drug for the treatment of HCU in 2007. (Orphanet)</p>
Onset	<p>All forms of the condition are asymptomatic for the first few weeks of life More than 50% of cases are an early-onset phenotype The signs and symptoms typically develop within the first year of life. (Rarediseases.info) Some mildly affected people may not develop features until later in childhood or adulthood. (Rarediseases.info)</p>	<p>DBS test has a low false-positive rate or a high PPV</p>	<p>The therapeutic strategy changes the prognosis for all forms of the condition Pre-symptomatic initiation results in better outcomes If the disease is diagnosed in the newborn infant, the treatment may ensure the development of normal intelligence and prevent the development of other complications. If treatment starts later, it can prevent life-endangering thromboembolic events and further escalation of the complications.</p>
Frequency	<p>Incidence/prevalence is $\geq 1/150,000$ and $< 1/100,000$ Prevalence is 1:144,000 in the UK. (expandedscreening.org)</p>		

Table A5. Isovaleric acidaemia (IVA), 8.5 points.

Condition (2.5 out of 6 Points)		Screening (3 out of 3 Points)		Treatment (3 out of 4 Points)					
Severity	The disorder only has severe forms	0	Availability	DBS test is available and in use	2	Availability	An EMA-approved treatment is available	0	
	There is a rapidly progressing form	0.5		DBS test is not yet available, but is in development with published evidence	0		OR	A treatment intervention is available (diet, HSCT, BMT)	1
	The disorder can be fatal by adolescence	1		DBS test has a low false-positive rate and/or a high PPV	1		OR	A treatment is in late development (phase 3)	0
Onset	All forms of the disorder are asymptomatic for the first few weeks of life	0	Performance	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance	0	A treatment is in early development (preclinical, phase 1, or phase 2)		0	
	More than 50% of cases are an early-onset phenotype	0		Outcomes	The treatment strategy changes the prognosis for all forms of the disorder	0			
Frequency	Greater than or equal to 1 in 50,000	0	The treatment strategy changes the prognosis for some forms of the disorder		1	OR			
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	0	The treatment strategy does not change prognosis or improves only some symptoms of the disorder		0	AND			
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	1	Pre-symptomatic initiation results in better outcomes		1				
	Between 1 in 250,000 and 1 in 150,000	0							

Table A6. IVA Scoring.

	Condition	Screening	Treatment
Severity	<p>There is a rapidly progressing form About half of babies identified through newborn screening have a very mild deficiency that remains asymptomatic and requires no therapy. (Rarediseases.org) Acute presentation progresses to coma. Two major clinical scenarios are often described, an acute form and a chronic intermittent form, but in reality the disease is best thought of as a continuous spectrum from asymptomatic to life threatening. (Rarediseases.org)</p>	<p>DBS test is available and in use</p>	<p>A therapeutic strategy is available (diet, HSCT, BMT) Lifelong management is with a low protein diet. (Orphanet)</p>
Onset	<p>All forms of the condition are asymptomatic for the first few weeks of life More than 50% of cases are an early-onset phenotype Acute, neonatal presentation is characterized by onset in the first two weeks of life. Later onset is relatively non-specific with failure to thrive and/or developmental delay. (Rarediseases.org) About half of babies identified through newborn screening have a very mild deficiency that remains asymptomatic and requires no therapy. (Rarediseases.org) The proportion of neonatal onset cases versus later onset cases is unknown.</p>	<p>DBS test has a low false-positive rate or a high PPV [23]</p>	<p>The therapeutic strategy changes the prognosis for all forms of the condition Pre-symptomatic initiation results in better outcomes If identified prior to the development of symptoms, outcomes are generally better, with normal growth and development. (Rarediseases) Patients who present symptomatically can have significant neurologic sequelae including neurodevelopmental delay, especially if acidosis and hyperammonemia are severe. (Orphanet)</p>
Frequency	<p>Incidence/prevalence is $\geq 1/150,000$ and $< 1/100,000$ Birth incidence is 0.83/100,000 (~1/120,000) [24]</p>		

Table A7. Medium-chain acyl-CoA dehydrogenase deficiency (MCADD), 11 points.

Condition (4.5 out of 6 Points)		Screening (3 out of 3 Points)		Treatment (3.5 out of 4 Points)					
Severity	The disorder only has severe forms	0	Availability	DBS test is available and in use	2	An EMA-approved treatment is available	0		
	There is a rapidly progressing form	0.5		AND	DBS test is not yet available, but is in development with published evidence	0	OR	A treatment intervention is available (diet, HSCT, BMT)	1
	The disorder can be fatal by adolescence	1	Performance	DBS test has a low false-positive rate and/or a high PPV	1	Availability	A treatment is in late development (phase 3)	0	OR
All forms of the disorder are asymptomatic for the first few weeks of life	1	AND		DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance	0		OR	A treatment is in early development (preclinical, phase 1, or phase 2)	0
Frequency	More than 50% of cases are an early-onset phenotype	0	Performance	DBS test has a low false-positive rate and/or a high PPV	1	Outcomes	The treatment strategy changes the prognosis for all forms of the disorder	1.5	
	Greater than or equal to 1 in 50,000	2					The treatment strategy changes the prognosis for some forms of the disorder	0	OR
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	0					OR	The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	0					Pre-symptomatic initiation results in better outcomes	1	AND
	Between 1 in 250,000 and 1 in 150,000	0							

Table A8. MCADD Scoring.

Condition	Screening	Treatment
Severity There is a rapidly progressing form The condition can be fatal by adolescence About 25% of undiagnosed patients die during their first presentation of a crisis. (Orphanet)	Availability DBS test is available and in use	Availability A therapeutic strategy is available (diet, HSCT, BMT) Diet: Strict avoidance of fasting is the primary objective. Medium chain triglycerides should be avoided but no other special dietary restrictions are required. (Orphanet)
Onset All forms of the condition are asymptomatic for the first few weeks of life More than 50% of cases are an early-onset phenotype - MCADD usually presents 3threeto 24 months after birth in previously healthy infants. (Orphanet) - Many affected individuals remain asymptomatic throughout life. (Orphanet)	Performance DBS test has a low false-positive rate or a high PPV [25]	Outcomes The therapeutic strategy changes the prognosis for all forms of the condition Without treatment MCADD can be fatal. About 25% of undiagnosed patients die during their first presentation of a crisis. (Orphanet) Pre-symptomatic initiation results in better outcomes
Frequency Incidence/prevalence is $\geq 1/50.000$ MCADD is estimated to affect up to 1/10,000 babies born in the UK. (www.nhs.uk/conditions/mcadd , accessed on 31 May 2021)		

Table A9. Maple syrup urine disease (MSUD), 9 points.

Condition (2.5 out of 6 Points)		Screening (3 out of 3 Points)		Treatment (3.5 out of 4 Points)					
Severity	The disorder only has severe forms	0	Availability	DBS test is available and in use	2	An EMA-approved treatment is available	0		
	There is a rapidly progressing form	0.5		AND	DBS test is not yet available, but is in development with published evidence	0	OR	A treatment intervention is available (diet, HSCT, BMT)	1
	The disorder can be fatal by adolescence	1		Performance	DBS test has a low false-positive rate and/or a high PPV	1	Availability	A treatment is in late development (phase 3)	0
All forms of the disorder are asymptomatic for the first few weeks of life	0	AND	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance		0	OR		A treatment is in early development (preclinical, phase 1, or phase 2)	0
Onset	More than 50% of cases are an early-onset phenotype	0	Outcomes			The treatment strategy changes the prognosis for all forms of the disorder	1.5		
	Greater than or equal to 1 in 50,000	0				The treatment strategy changes the prognosis for some forms of the disorder	0	OR	
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	1		OR			The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0	
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	0				Pre-symptomatic initiation results in better outcomes	1	AND	
	Between 1 in 250,000 and 1 in 150,000	0							

Table A10. MSUD Scoring.

	Condition	Screening	Treatment
Severity	<p>There is a rapidly progressing form. The condition can be fatal by adolescence Classic MSUD: If untreated, progressive brain damage is inevitable and death occurs usually within weeks or months. (Rarediseases.org)</p>	<p>DBS test is available and in use</p>	<p>A therapeutic strategy is available (diet, HSCT, BMT) The treatment of classic, intermediate, intermittent, and thiamine-responsive MSUD has three chief components: 1. Lifelong therapy to maintain an acceptable diet; 2. Life-long maintenance of normal metabolic conditions including the levels of the BCAAs in the body; 3. immediate medical intervention for metabolic crises. (Rarediseases) Even if affected individuals follow the specialized diet strictly, the risk of metabolic crisis always remains. (Rarediseases)</p>
Onset	<p>Onset of classic MSUD (50–75% of cases) (Orphanet) occurs in the neonatal period, usually within the first 24–48 h of life. (https://www.ncbi.nlm.nih.gov/gtr/conditions/C0024776, accessed on 31 May 2021)</p>	<p>DBS test has a low false-positive rate or a high PPV [24]</p>	<p>The therapeutic strategy changes the prognosis for all forms of the condition. Pre-symptomatic initiation results in better outcomes If identified prior to the development of symptoms, outcomes are generally better, with normal growth and development. (Rarediseases) Patients who present symptomatically can have significant neurologic sequelae including neurodevelopmental delay, especially if acidosis and hyperammonemia are severe. (Orphanet)</p>
Frequency	<p>Incidence/prevalence is $\geq 1/150,000$ and $< 1/100,000$ Birth incidence is 0.74/100,000 (~1/137,000) [24]</p>		

Table A11. Phenylketonuria (PKU) 11.5 points.

Condition (4.5 out of 6 Points)		Screening (3 out of 3 Points)		Treatment (4 out of 4 Points)					
Severity	The disorder only has severe forms	0	AND	Availability	DBS test is available and in use	2	OR	An EMA-approved treatment is available	1.5
	There is a rapidly progressing form	0.5			DBS test is not yet available, but is in development with published evidence	0		A treatment intervention is available (diet, HSCT, BMT)	0
	The disorder can be fatal by adolescence	0			DBS test has a low false-positive rate and/or a high PPV	1		A treatment is in late development (phase 3)	0
Onset	All forms of the disorder are asymptomatic for the first few weeks of life	1	AND	Performance	DBS test has a high false-positive rate and/or a low PPV and/or requires additional confirmatory strategies that are available to improve screening performance	0	OR	A treatment is in early development (preclinical, phase 1, or phase 2)	0
	More than 50% of cases are an early-onset phenotype	1			The treatment strategy changes the prognosis for all forms of the disorder	1.5			
Frequency	Greater than or equal to 1 in 50,000	2	OR				OR	The treatment strategy changes the prognosis for some forms of the disorder	0
	Greater than or equal to 1 in 100,000 and less than 1 in 50,000	0			The treatment strategy does not change prognosis or improves only some symptoms of the disorder	0			
	Greater than or equal to 1 in 150,000 and less than 1 in 100,000	0			Pre-symptomatic initiation results in better outcomes	1		AND	
	Between 1 in 250,000 and 1 in 150,000	0							

Table A12. PKU Scoring.

	Condition	Screening	Treatment
Severity	There is a rapidly progressing form	DBS test is available and in use	<p>An EMA-approved therapy is available</p> <p>- Palynziq is indicated for the treatment of patients with PKU aged 16 years and older who have inadequate blood phenylalanine control despite prior management with available treatment options.</p> <p>- Kuvan is indicated for the treatment of hyperphenylalaninaemia in adults and paediatric patients of all ages with PKU who have been shown to be responsive to such treatment.</p>
Onset	<p>All forms of the condition are asymptomatic for the first few weeks of life</p> <p>More than 50% of cases are an early-onset phenotype</p> <p>- Infants with PKU typically appear normal at birth. Symptoms develop within a few months of birth. (Orphanet)</p> <p>- Classical phenylketonuria is the most common form</p>	DBS test has a low false-positive rate or a high PPV	<p>The therapeutic strategy changes the prognosis for all forms of the condition</p> <p>Pre-symptomatic initiation results in better outcomes</p>
Frequency	<p>Incidence/prevalence is $\geq 1/50,000$</p> <p>Prevalence 1/10,000 live births in Europe (Orphanet)</p>
