

Supplementary material

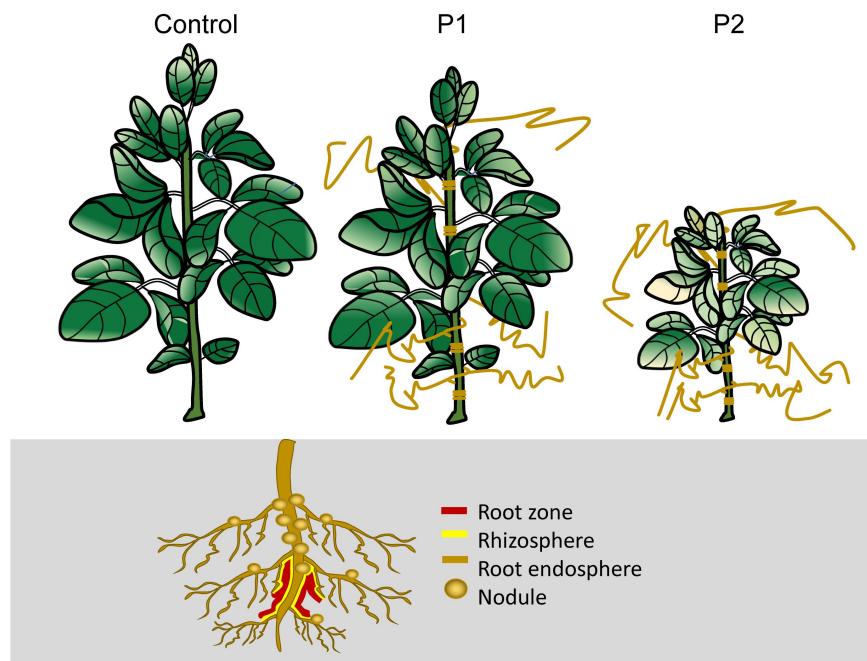

Figure S1. The sketch of three soybeans with three parasitism status (Control, P1, P2) and three rhizocompartments (root zone soil, rhizosphere soil and root endosphere).

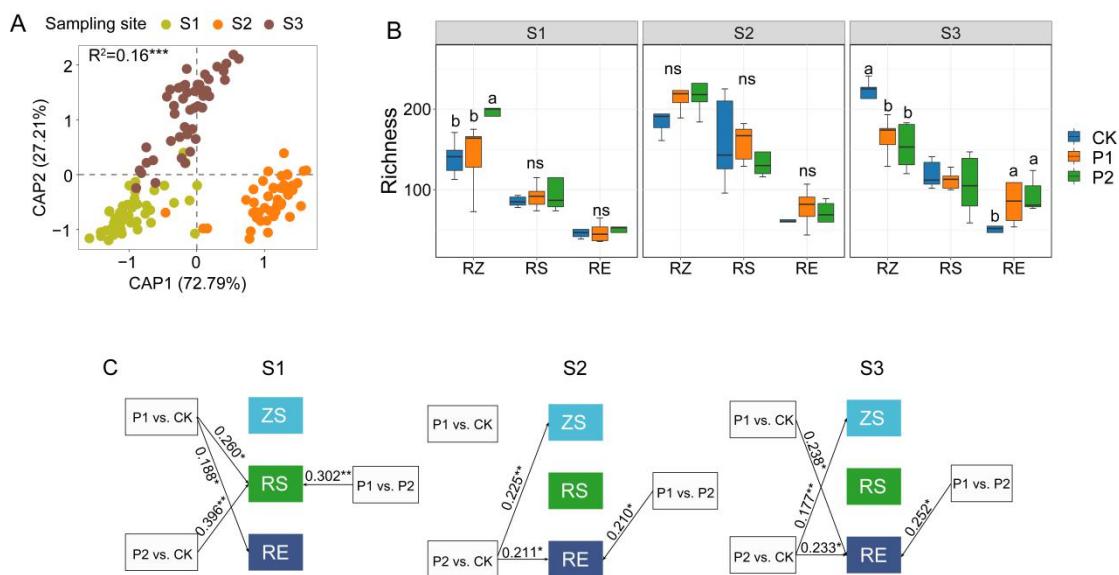

Figure S2. The effect of dodder parasitism on the root-associated fungal community of host in each sampling site. (A) Constrained analysis of principal coordinates (CAP) based on Bray-Curtis distances, showing the compositional variation explained by sampling site. (B) Boxplot showing differences in richness index among groups, with different letters indicating significant difference ($P < 0.05$). (C) Different effects of parasitism (P1 vs. CK, P2 vs. CK, P1 vs. P2) on the fungal communities of soybean in each sampling site. BS, Bulk soil; ZS, root zone soil; RS, rhizosphere

soil; RE, root endosphere, CK, control.

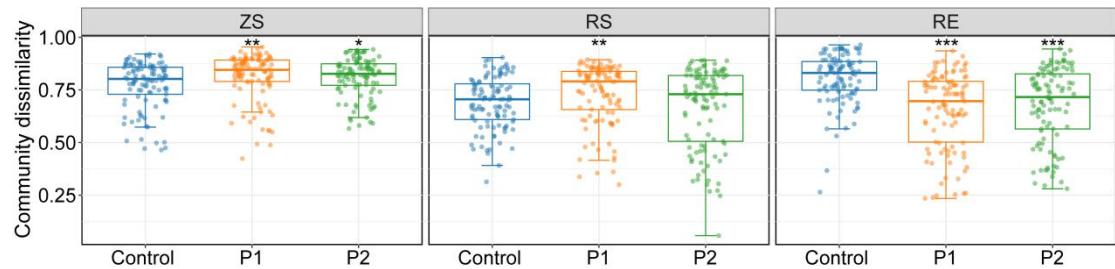

Figure S3. The variation in the dissimilarity (Bray-Curtis distance) of the fungal community in each root compartment among different parasitism statuses. ZS, root zone soil; RS, rhizosphere soil; RE, root endosphere.

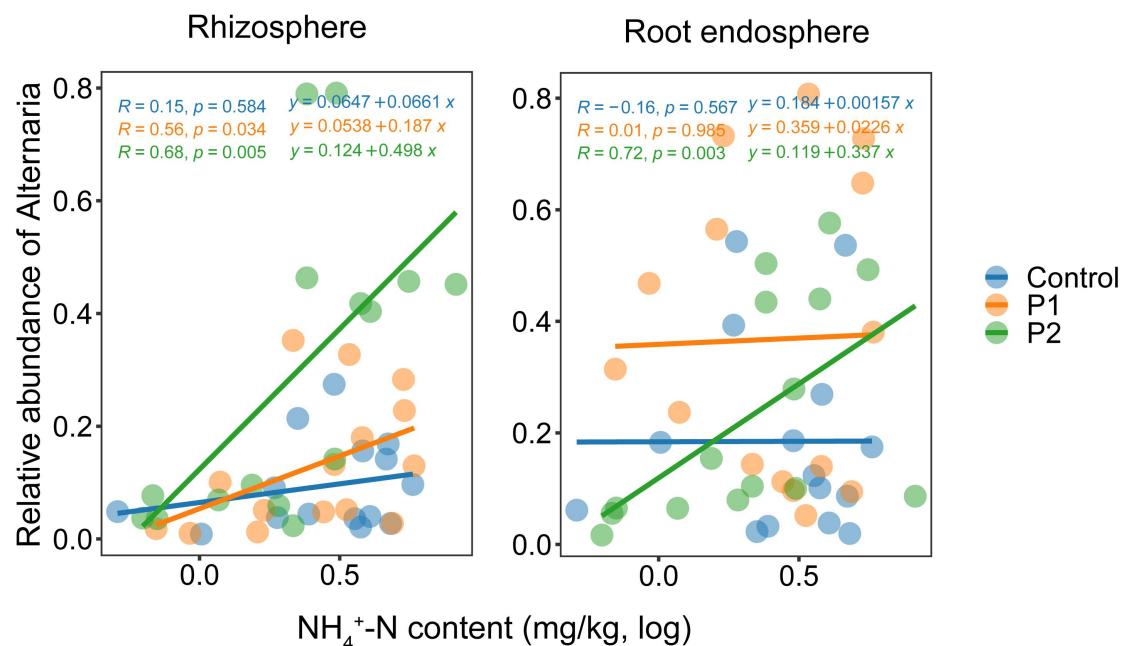

Figure S4. The relationship between soil NH_4^+ -N content and the relative abundance of *Alternaria*. The line represents the linear regression of the ordinary least squares model.

Table S1. The core flavonoid metabolites that significantly enriched under both P1 and P2 conditions based on the differential enrichment analysis and the K-means clustering analysis.
