Acknowledgements

This research was funded by Meat and Livestock Australia and the Australian Government through the Meat Donor Company, through an investment in 'Phosphorus management and requirements of tropical legume pasture swards' Project P.PSH.1050. Jane Carruthers, Emma Flavel and Calista McLachlan are thanked for their technical assistance.

Supplementary Material

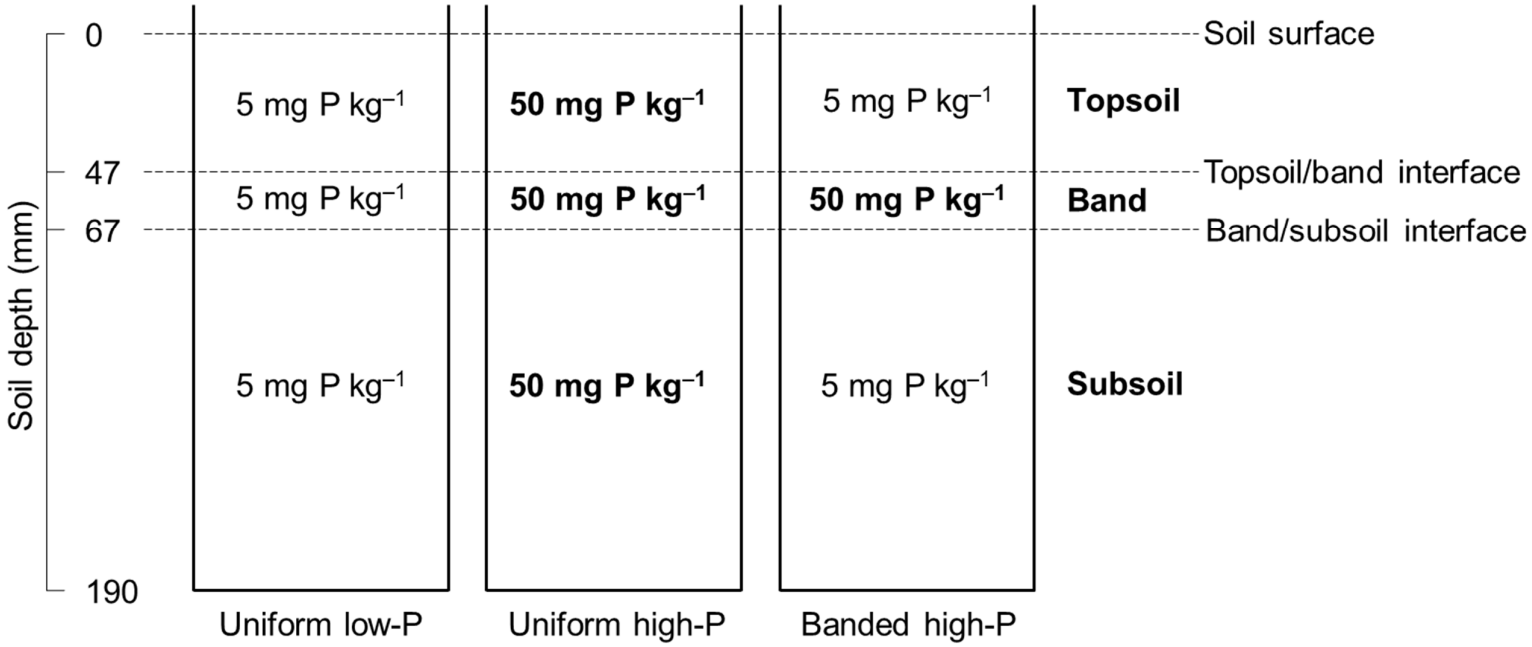

Figure S1. Diagrammatic illustration of the three soil-P distribution treatments used to investigate the root morphology and P acquisition of four warm-season pasture species. Thick lines represent the pot confine whereas dashed lines represent the soil surface and soil layer interfaces. The 5 and 50 mg P kg^{-1} labels depict the amount of P that was applied to each soil layer (i.e. topsoil, band and subsoil). The P applied to the 'band' layer was labelled with ~10.5 MBq kg^{-1} of ^{32}P-radioisotope tracer.
