Supplementary information

An ELISA using synthetic mycolic acid based antigens with DIVA potential for diagnosing for Johne's disease in cattle

Paul S. Mason, Thomas Holder, Natasha Robinson, Brendan Smith, Rwoa'a T. Hamed, Juma'a R. Al Dulayymi, Valerie Hughes, Karen Stevenson, Gareth J. Jones, H. Martin Vordermeier, Shawn Mc Kenna, and Mark S. Baird

Table S1: ELISA responses to six synthetic lipid antigens and sample information for PEI samples, together with faecal PCR cycle counts and responses in a commercial IDEXX MAP assay (0.55 recommended cut-off for positive).

MAP Faecal PCR Cycles	MAP IDEXX	Serum ID	map class	MOD171	JRRR121	RT237F2	SMP70	ZAM295	ST123

0	0.03	PEI 225	PEI F6	13.6	15.2	38.2	63.3	26.4	13.8

ELISA responses to six synthetic lipid antigens and sample information for PEI samples, together with faecal PCR cycle counts and responses in a commercial IDEXX MAP assay 0.55 (recommended cut-off for positive). A faecal PCR score of 0 corresponds to no response after 50 cycles.

Table S2: ELISA responses (% positive control) to six synthetic lipid antigens and sample information for APHA timeline samples (10 animals at 9 times). Columns 2 and 3 are results for commercial Bovigam IGRA and ParaTB IDEXX assays.

ELISA responses (% positive control) to six synthetic lipid antigens and sample information for APHA timeline samples (10 animals at 9 times). Columns 2 and 3 are results for commercial Bovigam IGRA and ParaTB IDEXX assays. * O.D values from a Bovigam IGRA assay, derived from overnight stimulation of whole blood with PPDA minus a Nil (RPMI only) value; PPDB assays were also carried out.   An animal is considered bTB positive if the O.D values of PPDB-PPDA is greater than 0.1 O.D on the Bovigam ELISA; within the limits of the assay, none of these animals were above that value. No IGRA assays were carried out at week 47. ** Values of above 55 are considered positive; those between 45 and 55 are intermediate and those below 45 are negatives.

Table S3: ELISA responses (% positive control) to six synthetic lipid antigens for APHA and Moredun samples

Median ELISA responses for each set of samples with each of six antigens as % positive control for that antigen. Optimal cut-offs are based on 16 PEI culture and IDEXX positive samples (PEI++) compared to all 80 PEI F5 and F6 negatives (again as % positive control), and sensitivity and specificity of each group based on those cut-offs. ROC analysis of these data is presented graphically in Fig S2. In some cases, such as for MOD171, the optimal cut-off by ROC analysis led to a very low specificity; cut-offs were then identified to give maximum accuracy (average of sensitivity and specificity) at >93 % specificity. The final five columns show the median calculated negative or positive status (on 0 to 1 scale) of PEI++ compared to all 80 F5 and F6 negative samples, combining results with several specified antigens using the R statistics package. These calculated values for each serum sample have then been analysed by ROC (shown graphically in Fig S2) and optimal cut-offs determined to provide the highest accuracy (average of sensitivity and specificity). Again, where the ROC analysis gave a specificity of below 93%, the cut-off was adjusted to meet that value. The data for F5 and F6 samples are also presented separately, using the same cut-offs.

Figure S2: ROC analysis of ELISA responses for PEI++ samples compared to 80 F5 and F6 negatives

Median ELISA responses (as % positive control) and sensitivity/specificity for Moredun 'no history' samples and for each cohort of APHA serum samples, using the same cut-offs as determined in Table 1. PEI++ data show the corresponding sensitivity with the 16 PEI samples both positive to culture and giving IDEXX responses above the recommended cut-off for MAP infection. Specificity values for single antigens are determined from Table S4 using the cut-offs from Table 1. Specificity values for combinations of antigens using R for each cohort are calculated using the antigen

combinations determined in Table 1; the cut-off for R calculations are as in Table 1 and are on a scale 0 (negative) to 1 (positive), applied to the data in Tables S6 and S7

Figure S4: Box plots showing distribution of ELISA responses for each group of samples PEI++, F5 and F6 compared to Moredun and APHA cohorts
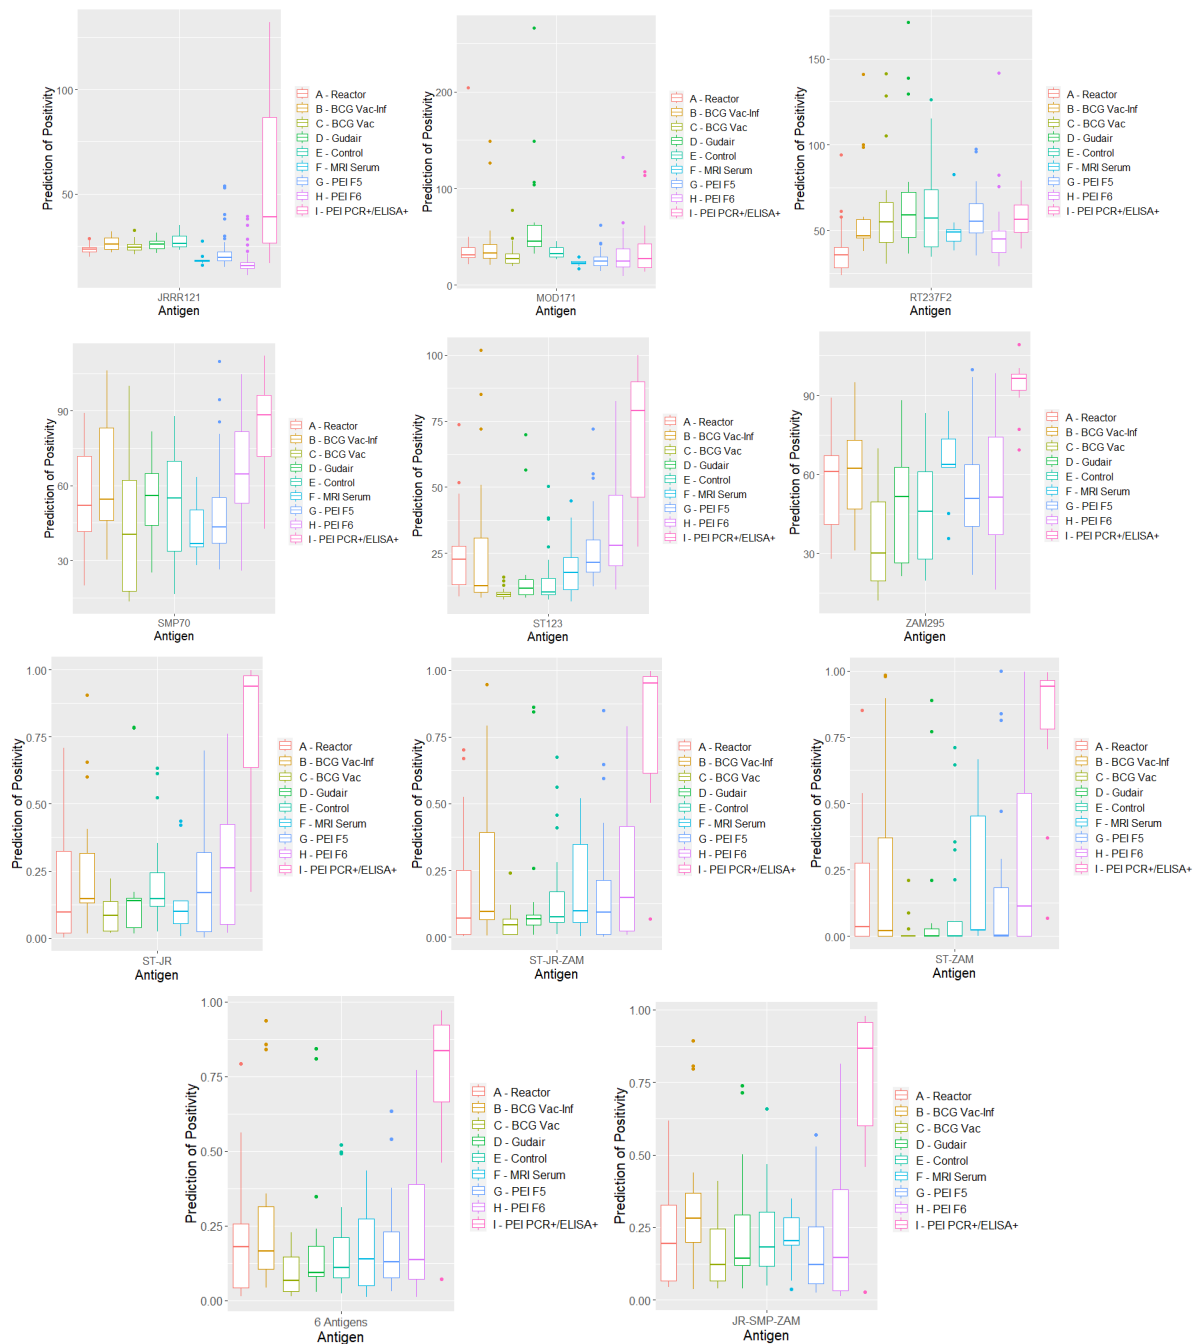

Table S6. Analysis of all 80 PEI PCR samples giving non-zero cycle counts (Table S1) with cut-offs optimised for maximum accuracy compared to all 80 F5 and F6 negatives.

Analysis of all 80 PEI PCR samples giving non-zero cycle counts (Table S1) with cut-offs optimised for maximum accuracy compared to all 80 F5 and F6 negatives. Cut-offs adjusted to give a minimum specificity with each antigen of 91 %, and with each antigen combination in R of 92.5 %. Data for F5 and F6 are then presented separately. Data for other cohorts of cattle analysed to the same cut-offs. Results with each other sub-set then analysed to same cut-offs and same antigen combinations in the R statistics package.
