

Supplementary Materials

Morphology of dome- and tepee-like landforms generated by expansive hydration of weathering anhydrite: a case study at Dingwall, Nova Scotia, Canada.

Adrian Jarzyna, Maciej Bąbel, Damian Ługowski, Firouz Vladi

Applied Sciences **2022**, *12*

Table S1: Inventory of hydration landforms with basic morphometric parameters and GPS locations.

Figure S1: Applied photogrammetric method – equipment, course of work and results.

Figure S2: Hydration landforms on the orthophotomaps and digital surface models.

Figure S3: Location of hydration landforms on the basemap of satellite image with characteristic of their sizes.

Figure S4: Location of hydration landforms with measured thickness of the detached layer on the basemap of satellite image.

Figure S5: Frequency distribution diagrams of morphometric parameters characterising hydration landforms.

Figure S6: Dependence of relative height of hydration landforms on length, width, bulge degree and coefficient of circularity.

Figure S7: Pattern of fractures within hydration forms.

Figure S8: Traces of fractures and rock layers on the orthophotomaps of the quarry bottom.

Figure S9: Exemplary hydration landforms influenced by structural types of bedrock.

Table S1
Inventory of hydration forms at Dingwall

* - thickness of elevated rock layer measured on photographs and in graphic program Corel Draw

 - lack of data  - hydration form documented by 3D or 2.5D model  - hydration form being part of 2.5D model of the quarry

 - domed hydration form  - tepee-shaped hydration form

Figure S1

Applied photogrammetric method – equipment, course of work and results.

Documentation of the Dingwall quarry bottom was made using aerial and terrestrial photogrammetry during two expeditions: September 10-26th, 2018 and August 15-29th, 2019. Three photographic devices were used in the field: the UAV (model: DJI Phantom 4 Advanced) and two models of cameras (fig. IB-D; III). In addition, a GPS receiver that supports RTK corrections (Real Time Kinematic) was used, for measuring control and checking points with an accuracy of approx. 1-2 cm (using the NAD_1983_MTM_4 coordinate system). Also, three sizes of portable boards made of PVC material were used to mark the checkpoints on the surface characterized by three sizes: 1) 42×45.5 cm (fig. IA); 2) 14×42 cm; 3) 10×61 cm printed with a unique graphic symbol generated in the Photoscan program. Also on the surface of the quarry bottom, in the case of selected fields, points were spray-painted to check the accuracy of the model fit to the coordinate system.

Fig. I. The selected equipment for the photogrammetry method applied at Dingwall; A – largest portable PCV board 42×45.5 cm used as a control point; B – Unmanned Aerial Vehicle DJI Phantom 4 Advanced; C – Nikon D7100; D – Olympus E-PL 6 Lite.

The UAV flight over the quarry was made with the approval of the Canadian Ministry of Transport. Seven areas were documented within three fields of the quarry (fig. II). Five areas were documented in 2018, two areas in 2019. Before the flight, boards serving as checkpoints (both in 2018 and 2019) and checking points (in 2019) were placed on the surface. The UAV flights for photogrammetric documentation were made at a height of 25 m above the ground. The adjacent photographs were taken with an overlap of 60-80%. During flight a pilot adjusted the height of 25 m precisely to the topography of the terrain. The flight procedure was performed using the DJI application installed on the mobile device.

Legend

- 42 location of hydration form with 2.5D or 3D models and its identifying number
- 7 part of quarry with aerial photogrammetric documentation and its identifying number
- extent of the quarry
- ∇ ∇ ∇ gypsum-anhydrite rocks visible on the satellite map
- 60 contours lines, interval 10 m
- roads
- vegetation
- waters
- other areas
- buildings

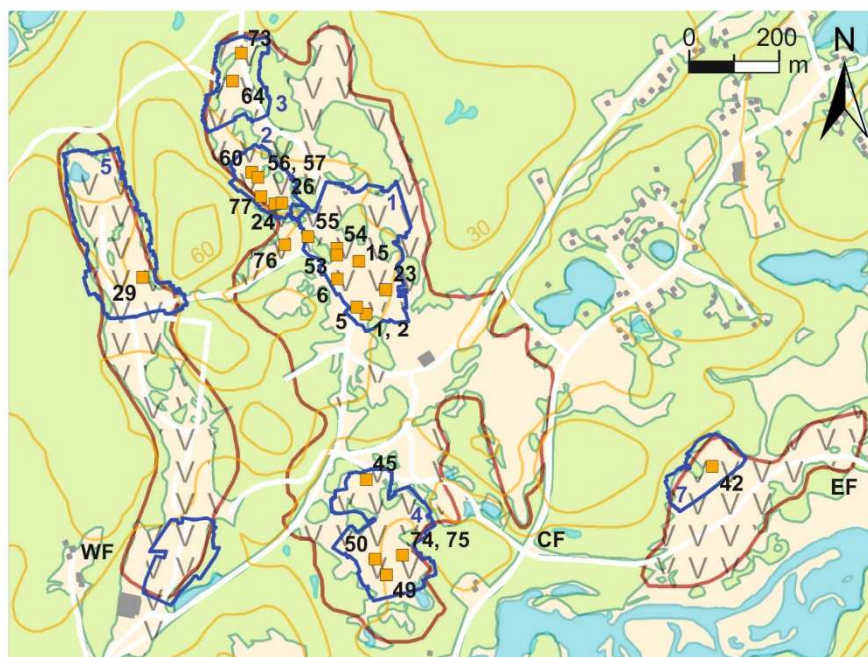

Fig. II. The topographic map of the quarry with marked parts with aerial photogrammetric documentation and hydration forms with terrestrial photogrammetric documentation.

Terrestrial photogrammetric documentation was made for 25 hydration forms in the form of 22 models (3 models include 2 adjacent forms; fig. II). Two selected hydration forms (form no. 1 and no. 6) were documented twice by making their models in 2018 and 2019. The cameras used: Nikon D7100 and Olympus PEN Lite E-PL 6 made it possible to photograph objects in the form of a RAW file, enabling further processing of photographs in a graphic program RawTherapee. The photographs were taken from three different heights located along the lines around the object and inside the cavity. The overlapping of individual shots was preserved in the range of approx. 60-80%. The photographs that needed correction were imported into RawTherapee, where a manual shadow adjustment, exposure correction, and brightening were initiated.

Photographs together with the collected control and checking points and GPS points became the basis for further work in the Photoscan photogrammetry program, based on the Structure from Motion tool (short: SfM), creating an object in 3D on the basis of overlapping photographs (Westoby et al. 2012). The program uses metadata stored in a JPEG image in the form of EXIF (Exchangeable Image File Format) containing information about the camera model, camera settings, shutter speed and focal length (Snaveley 2008). SfM uses the Bundle Adjustment algorithm in the object modeling process, enabling the location of the photograph and generation of the geometry of the object in 3D space (Snaveley 2008; Triggs et al. 2000).

The methodology of documentary photogrammetric works was described in the previous work of the authors (Jarzyna et al. 2020b) as well as in the instructions for the used program (AgiSoft 2016).

The photogrammetric works resulted in twenty six 3D models of hydration forms covering 0.23 ha and eight 2.5D models of fragments of the quarry area covering 27.55 ha. On the basis of each of them, orthophotomaps and DSMs were created separately with the parameters listed in the table (fig. IV). The average size of the DSM field pixel is 2.54 mm/px for 3D models of hydration forms and 33.60 mm/px for 2.5D models of the quarry bottom. The orthophotomap is characterized by the size of the field pixel at the average value of 0.623 mm/px for 3D models and 2.5D models. The data with above mentioned good quality of image resolution are the basis for further work in the ArcGIS program.

	Maps of study area	3D or 2.5 models		Aerial photogram.	Terrestrial photogrammetry

Figure S2

Hydration landforms on the orthophotomap and digital surface models with their extent, documentary number, azimuth of the elongation, entrance to the cavity, the heighest and the lowest elevation points and direction of maximum lateral expansion (the north direction in legend concerns all the maps).

Legend

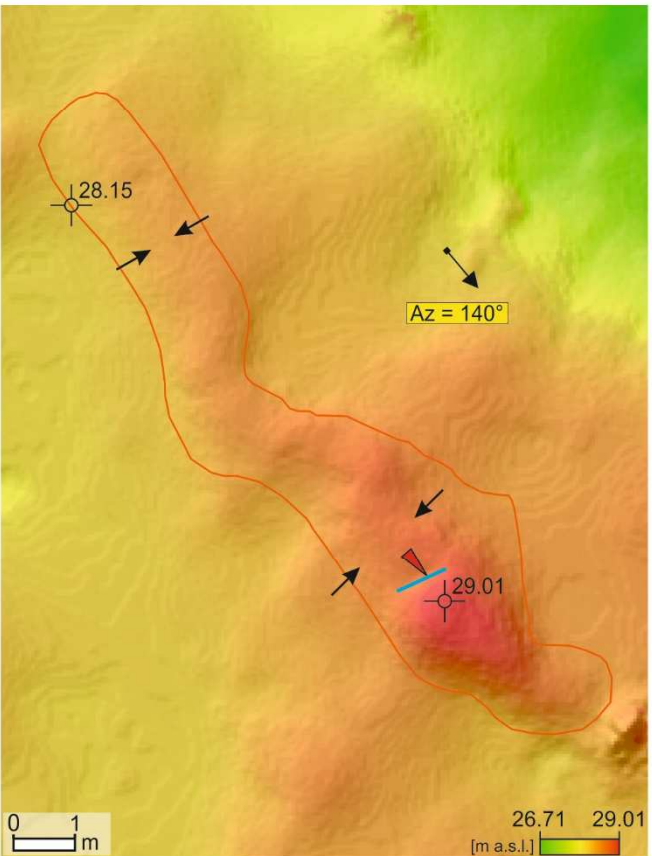

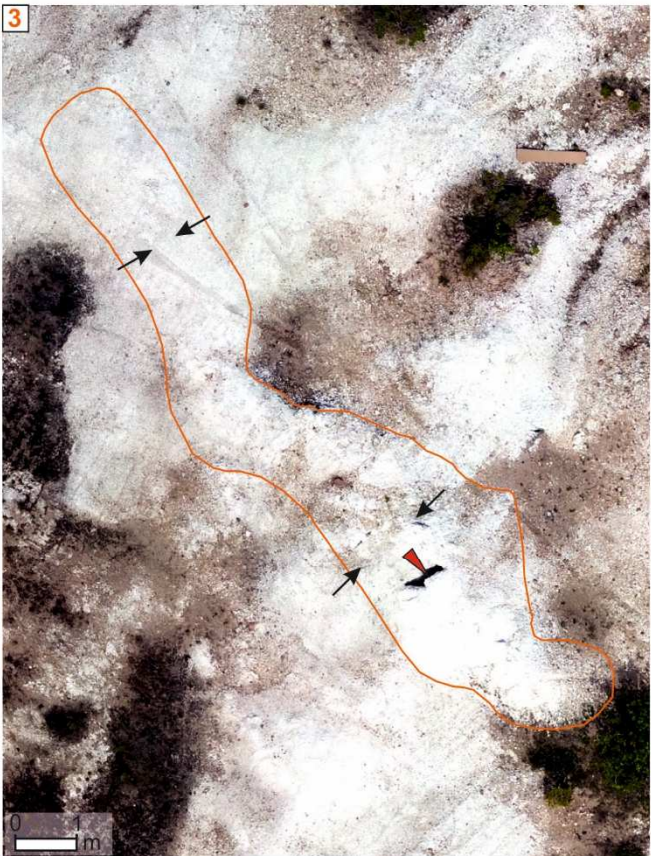

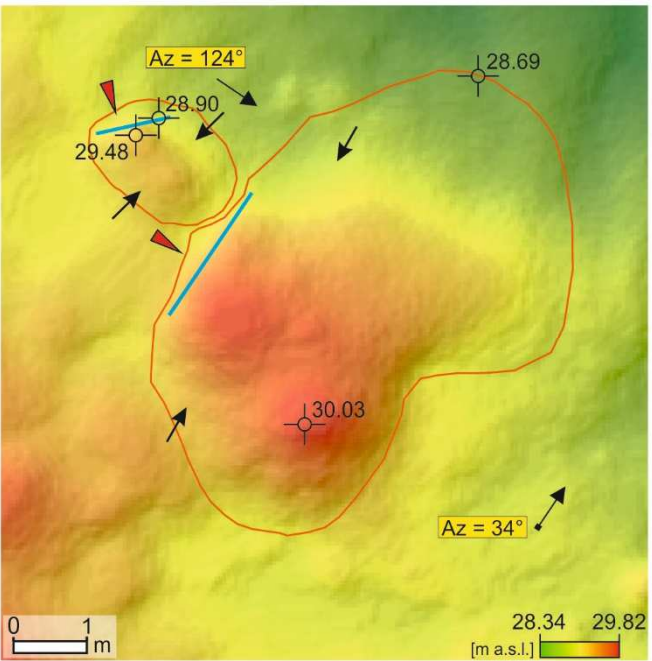

- 1

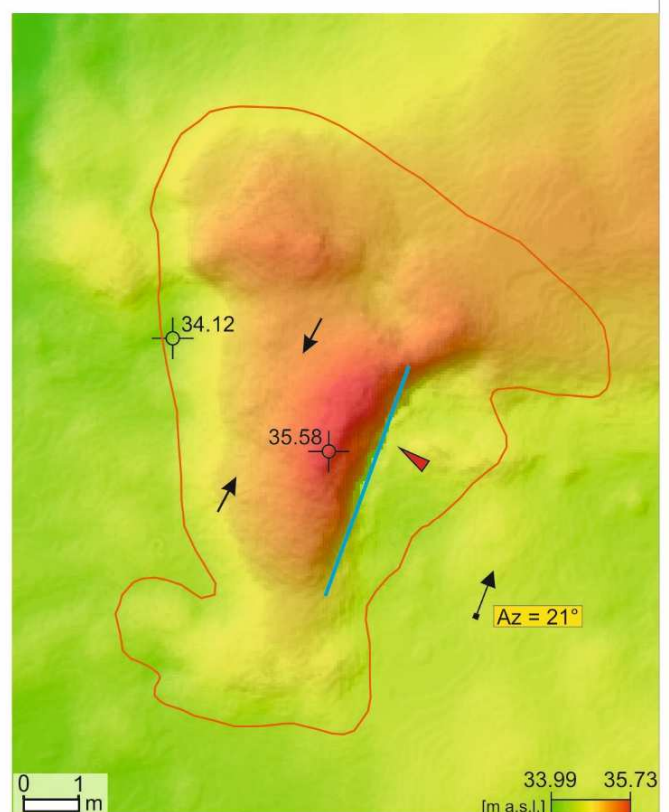

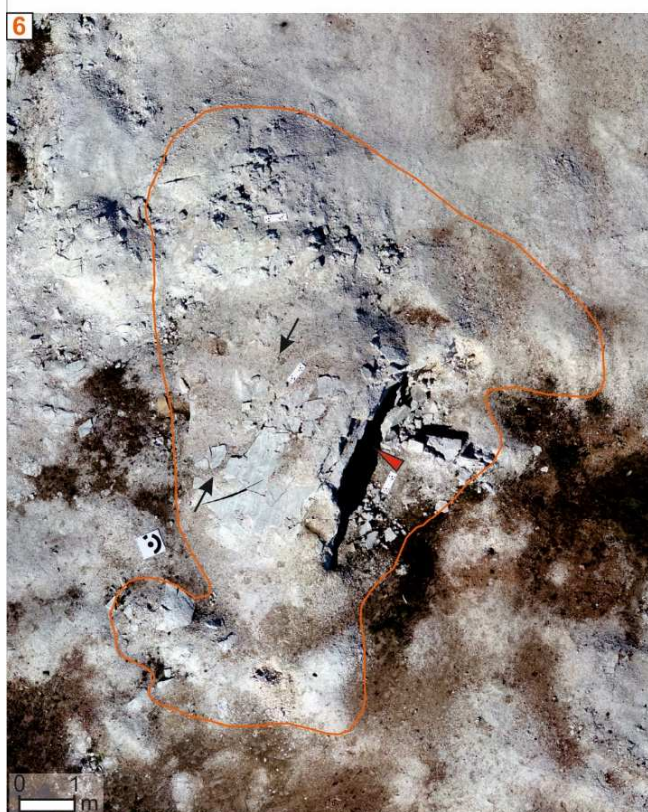

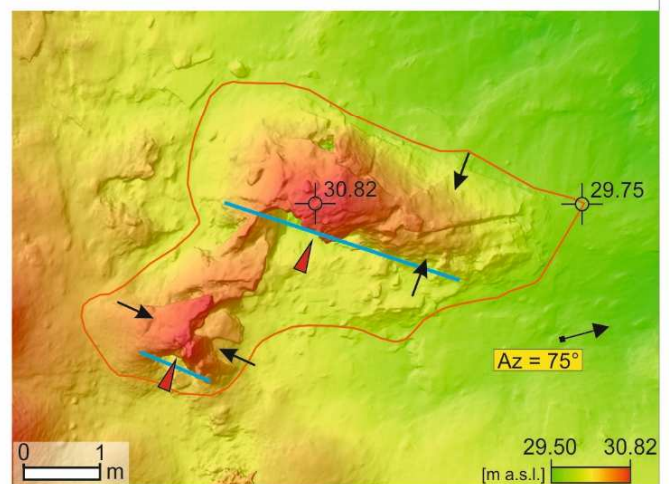

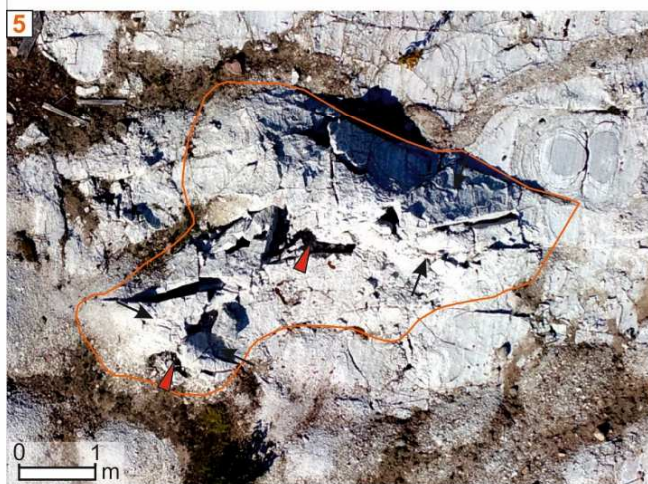

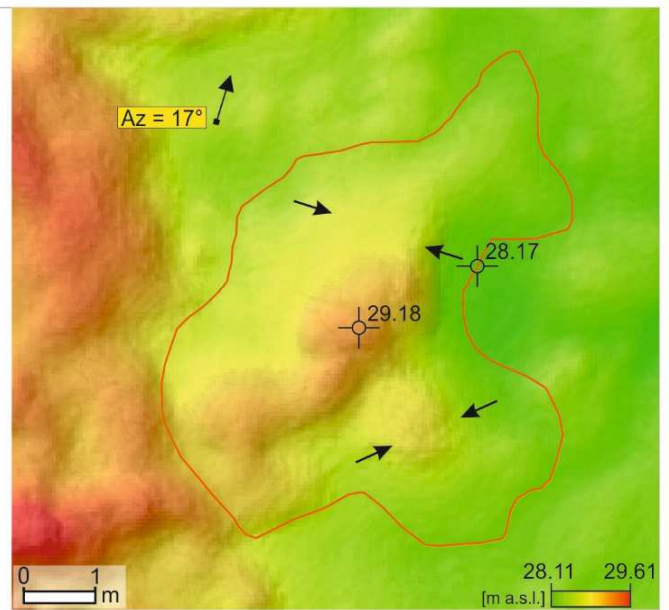

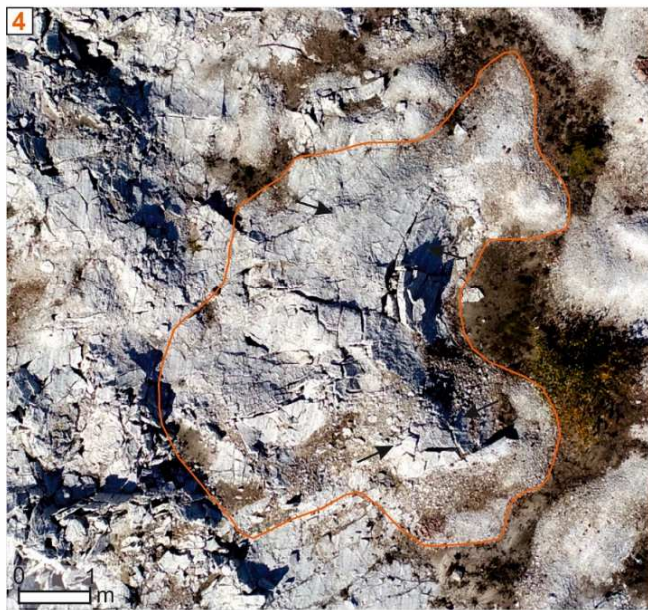

extent of the hydration form and its number
- Az

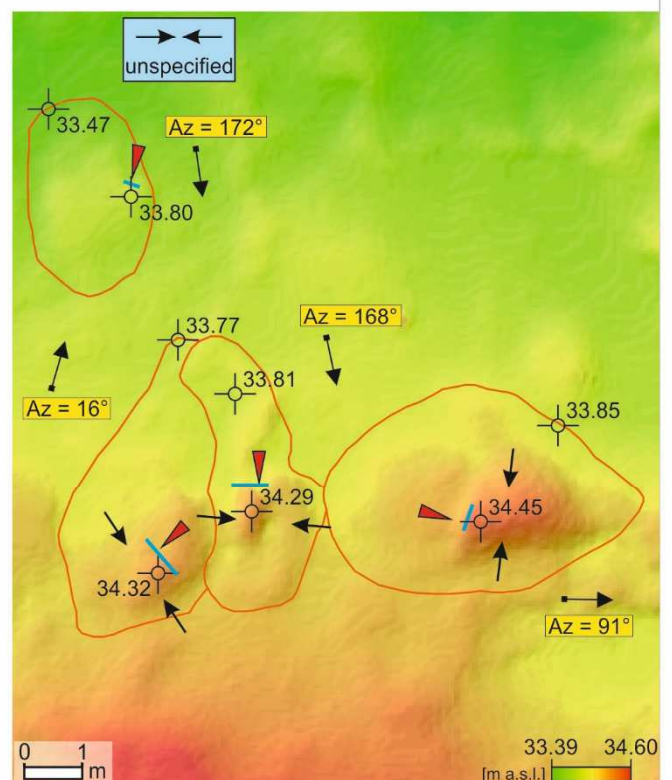

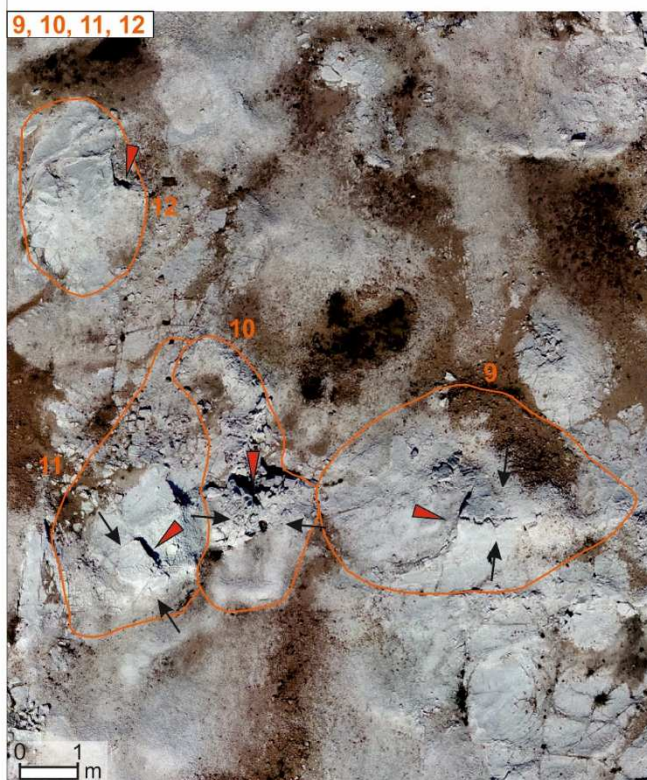

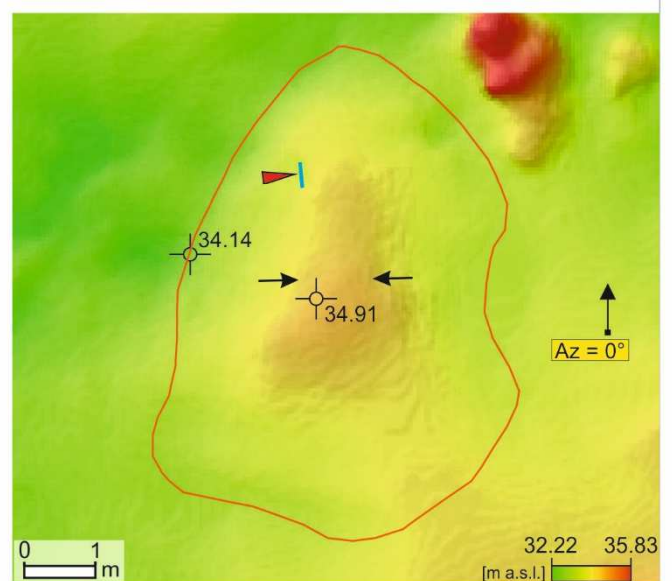

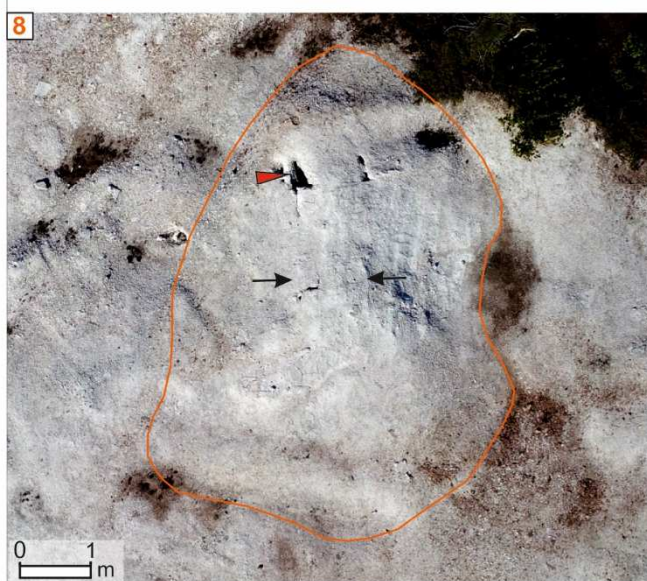

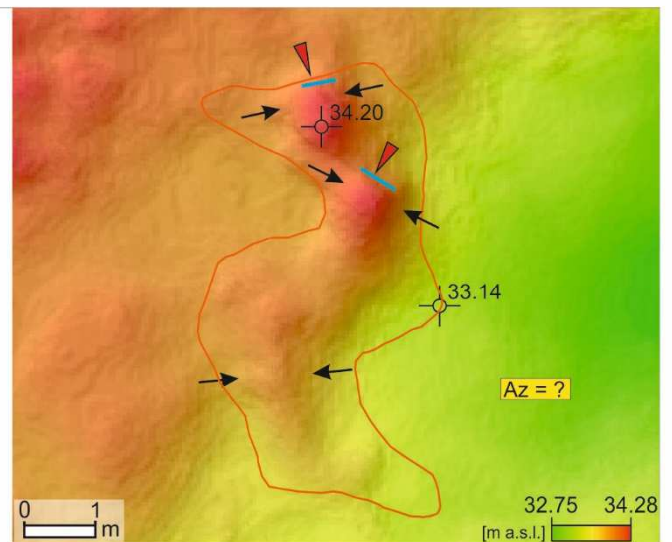

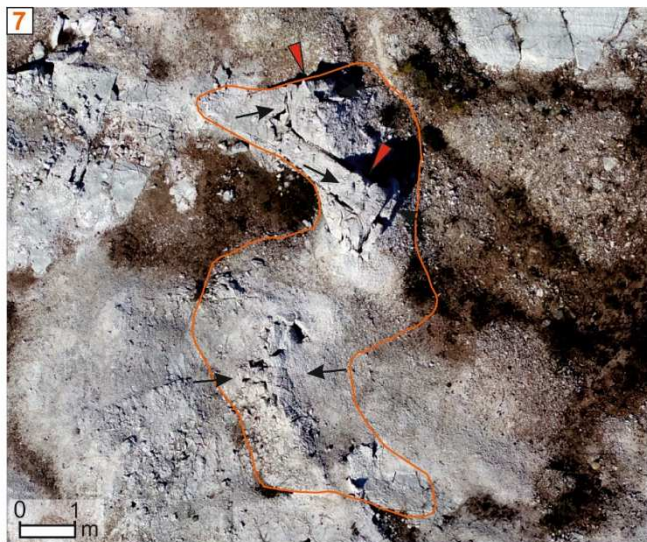

azimuth of the elongation
- direction of maximum lateral expansion
- entrance to the cavity or cave
- 184

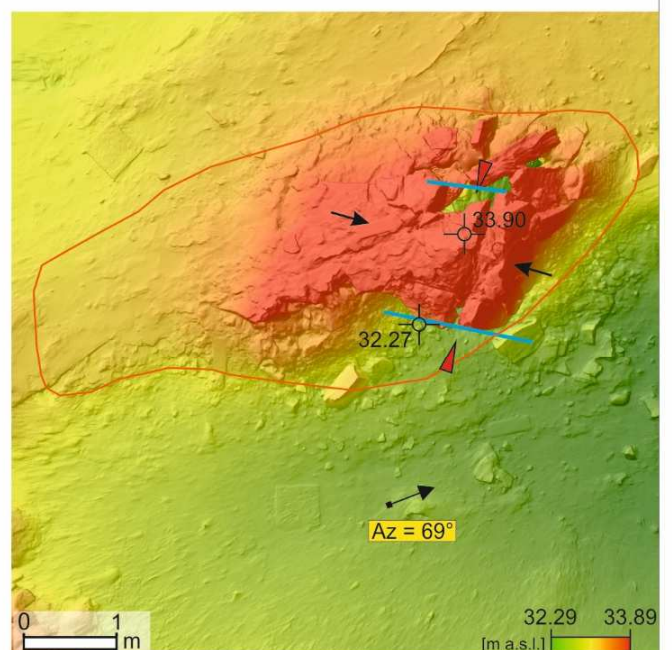

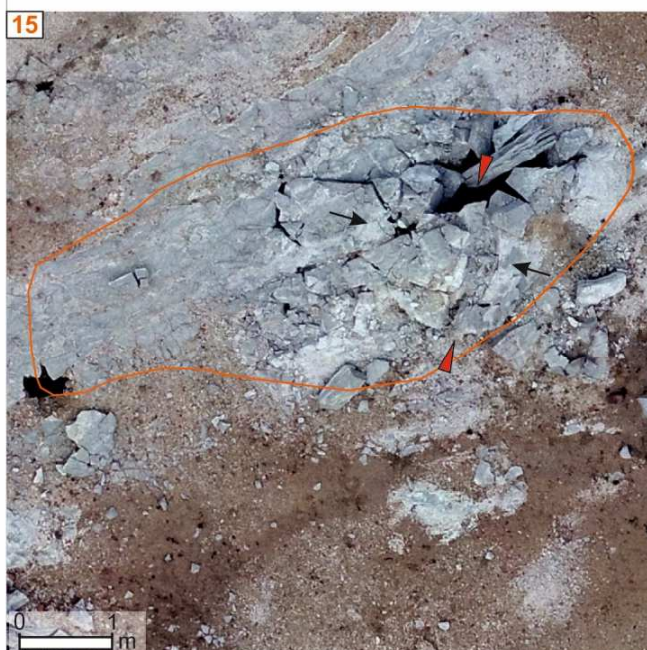

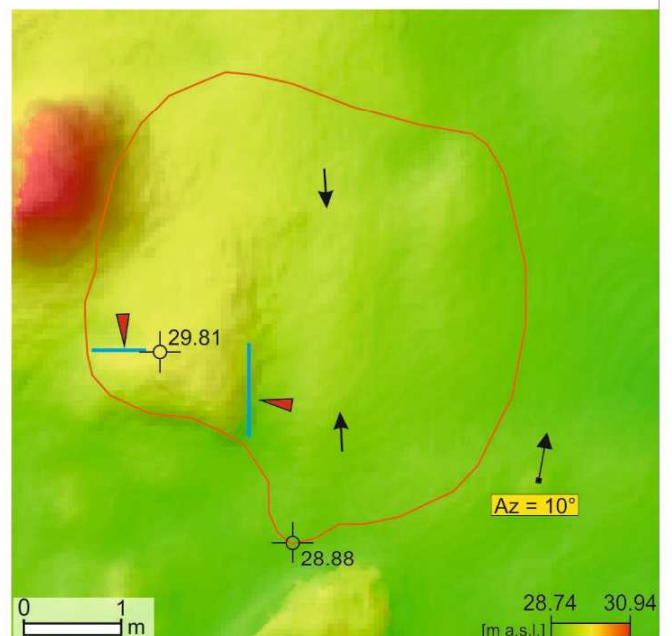

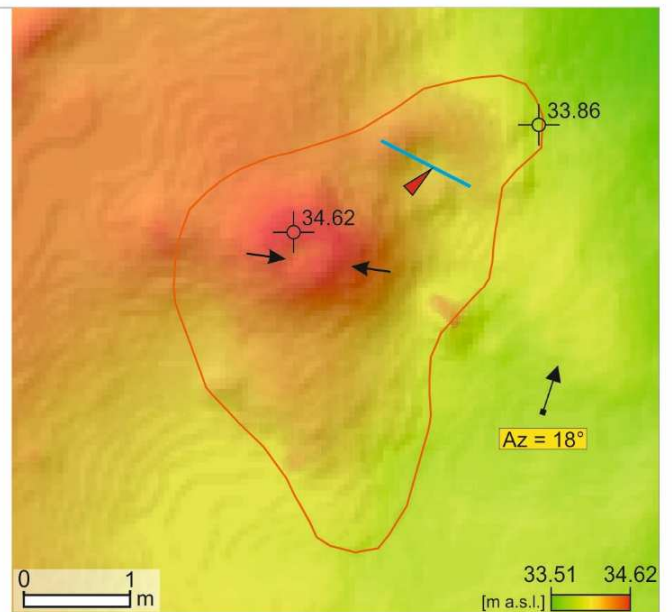

the highest and the lowest point within hydration form*
- entrance line to the cavity
- N

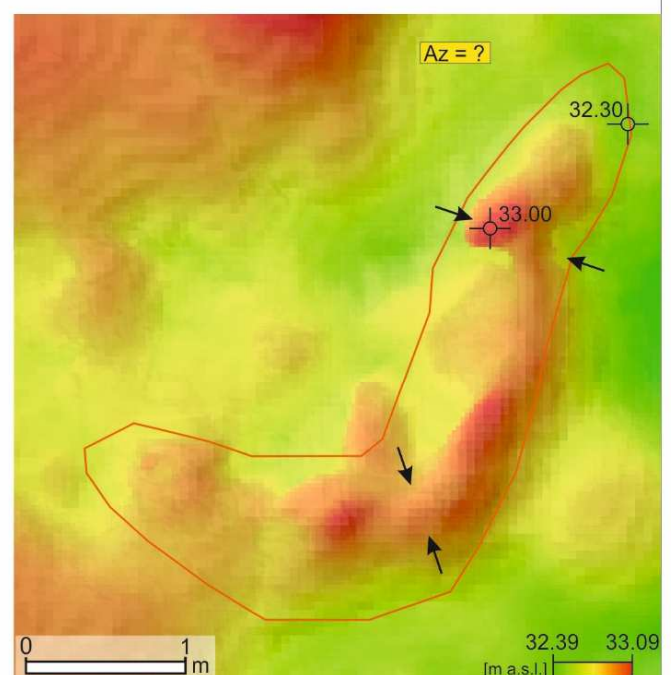

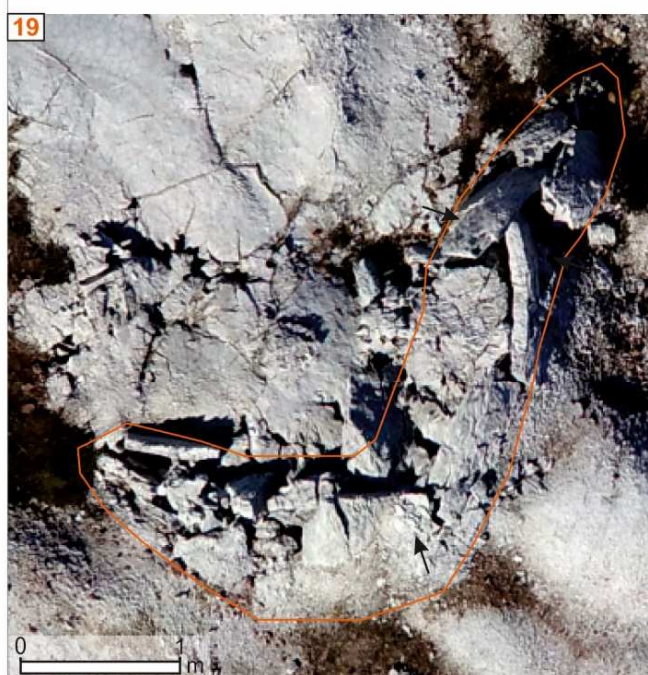

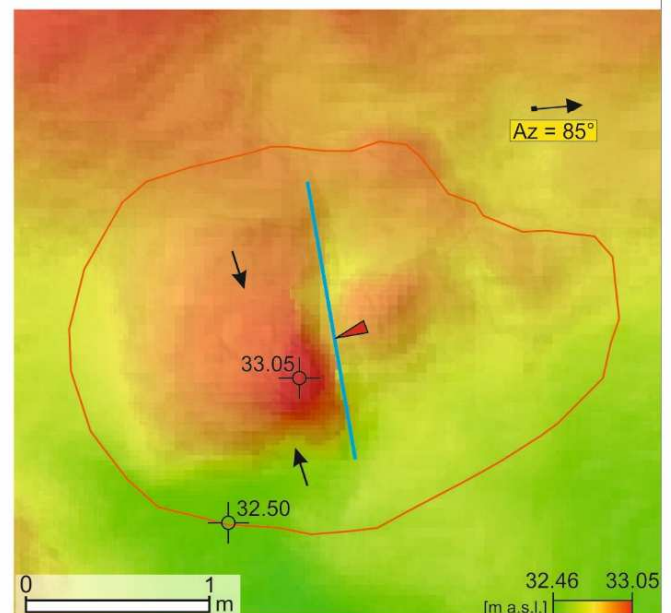

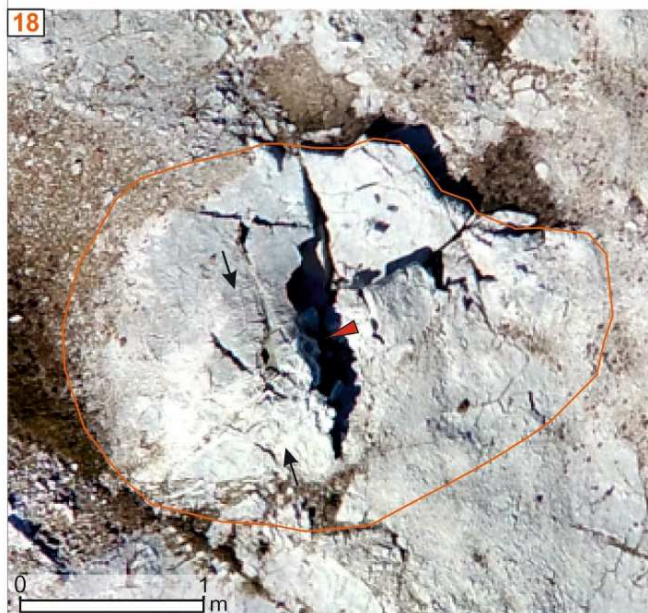

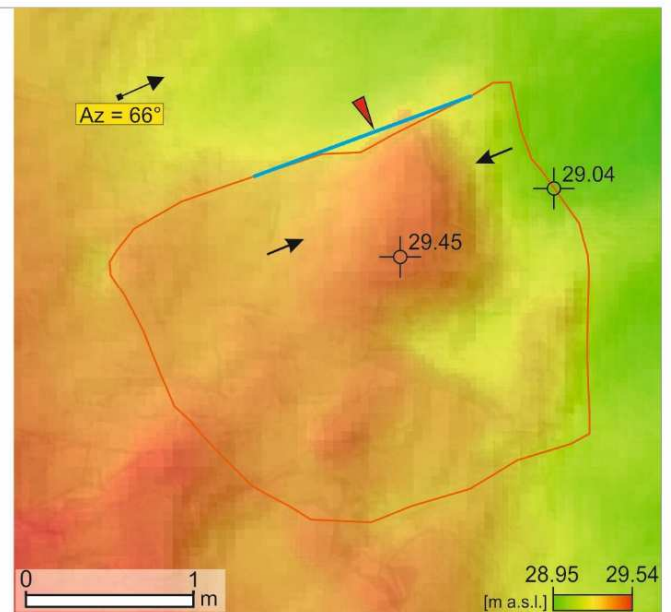

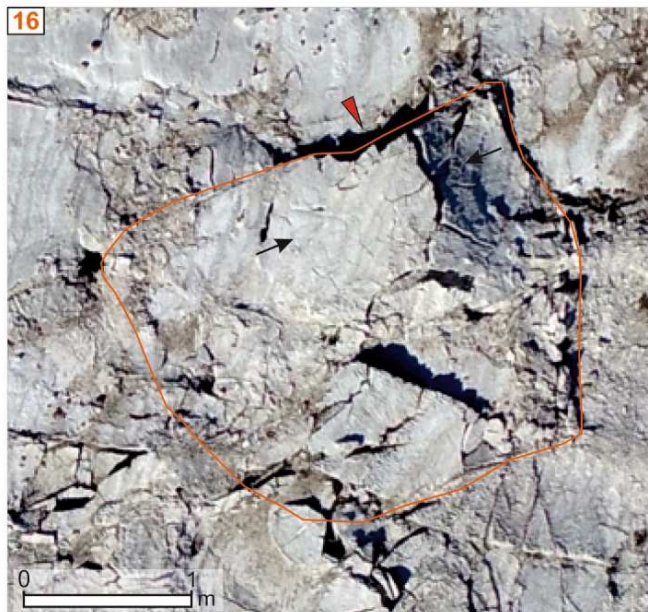

* - for selected forms documented with the model 3D or 2.5D (terrestrial photogrammetry) elevation points [m a.s.l.] were determined on the basis of these models

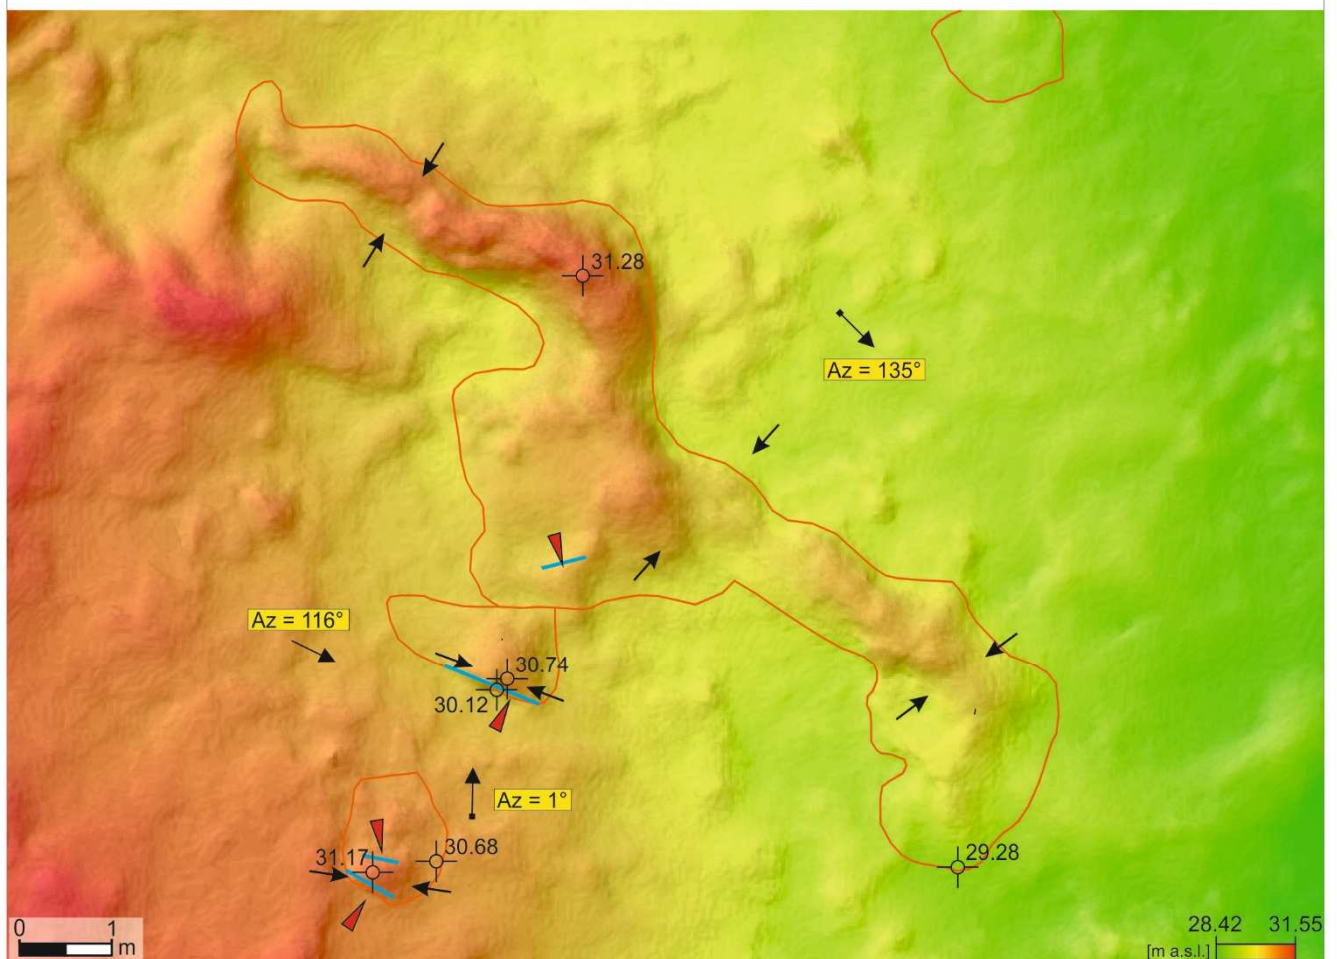

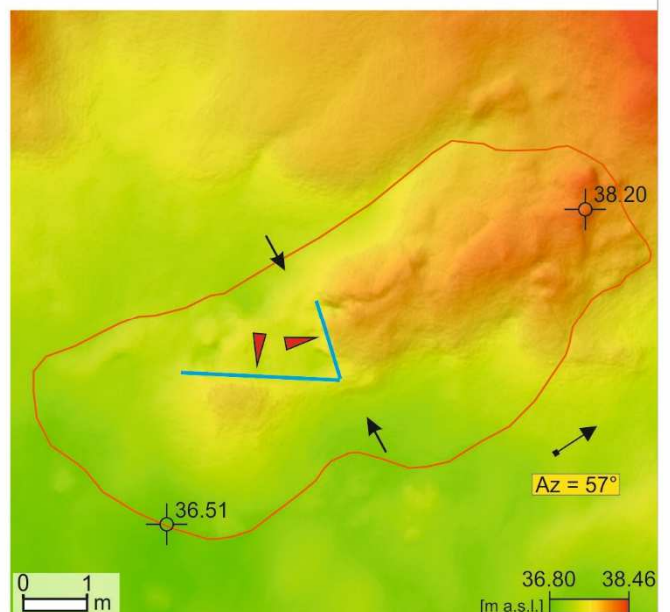

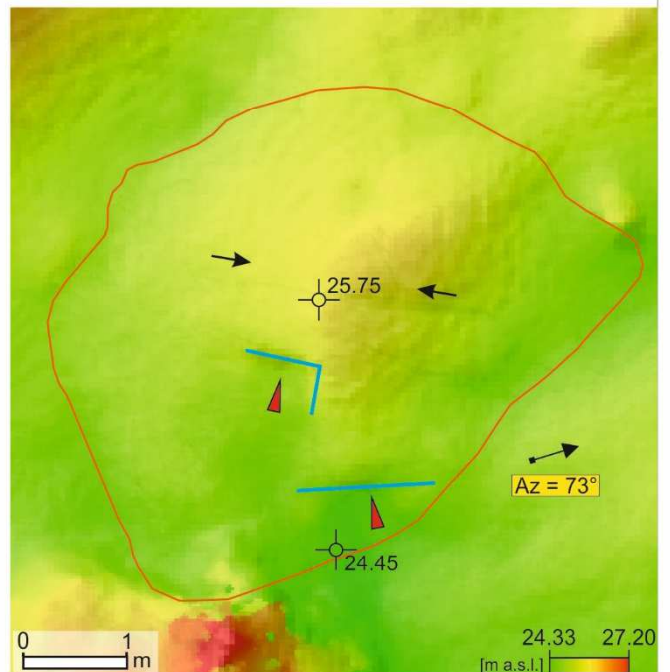

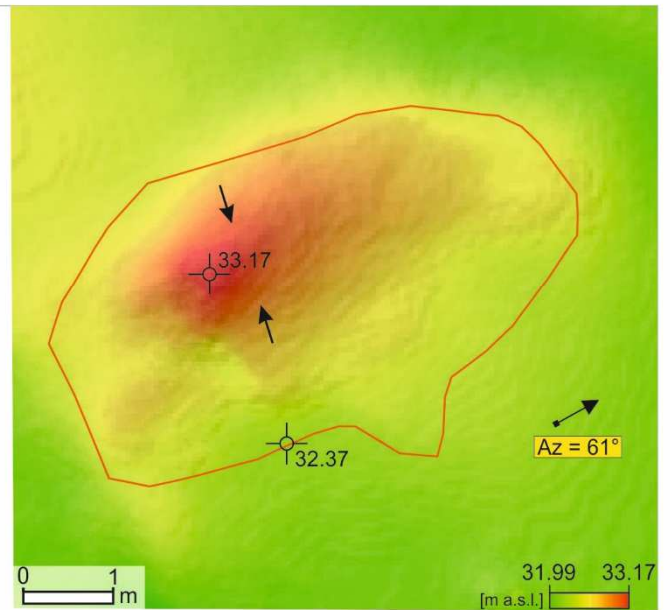

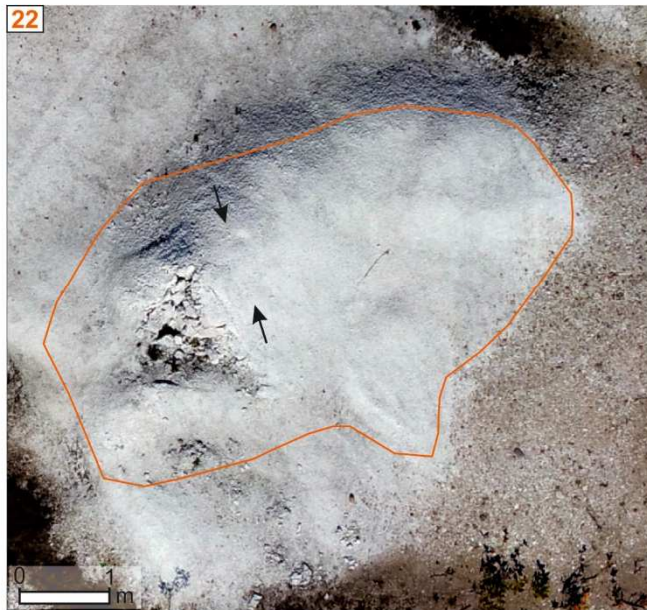

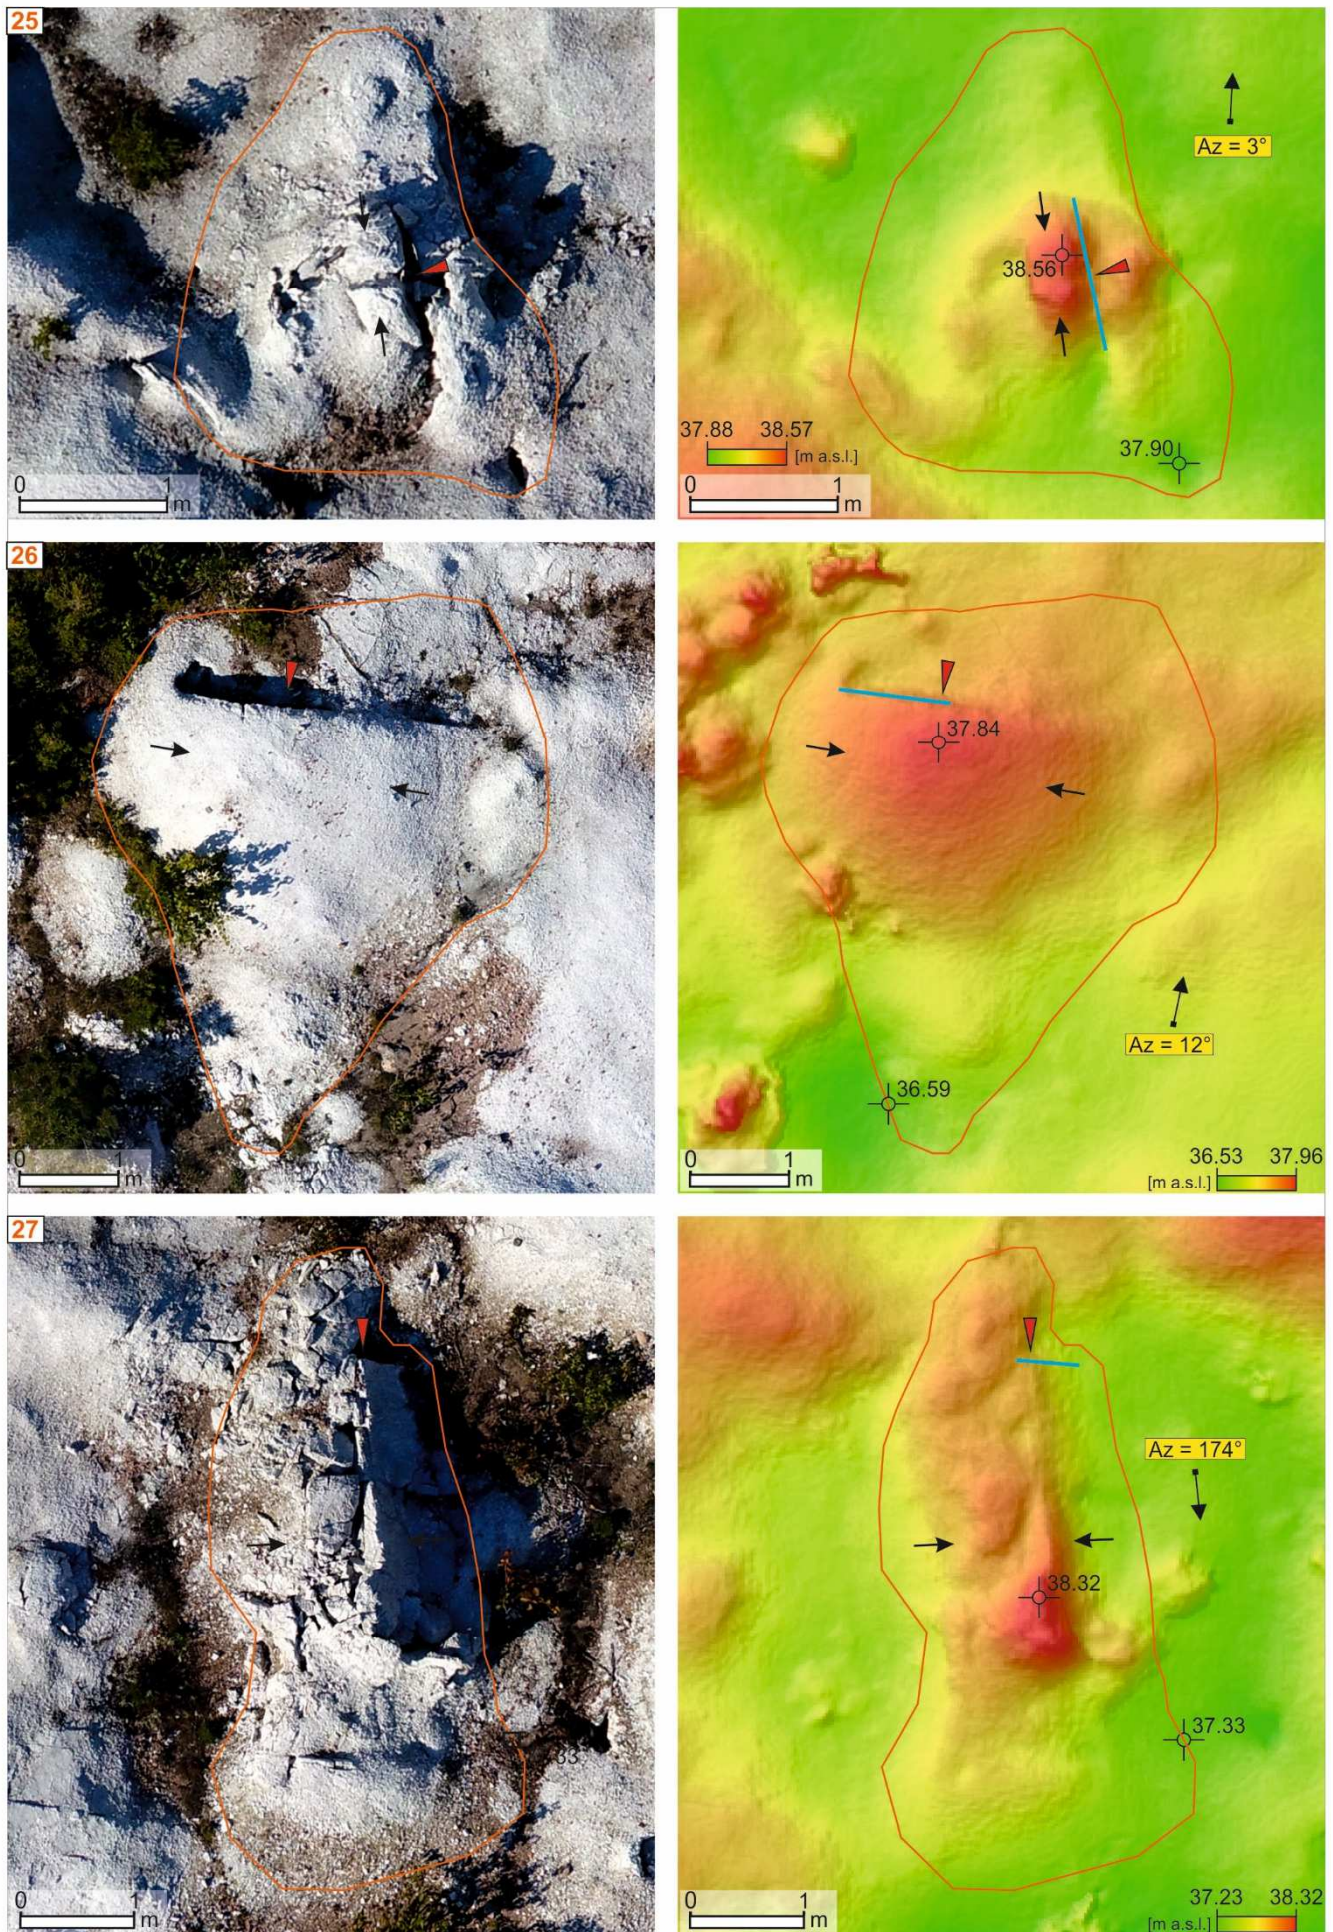

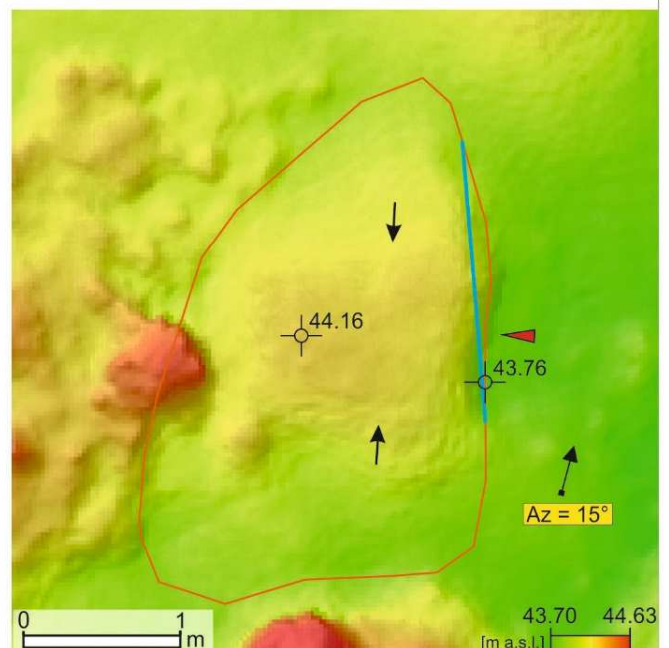

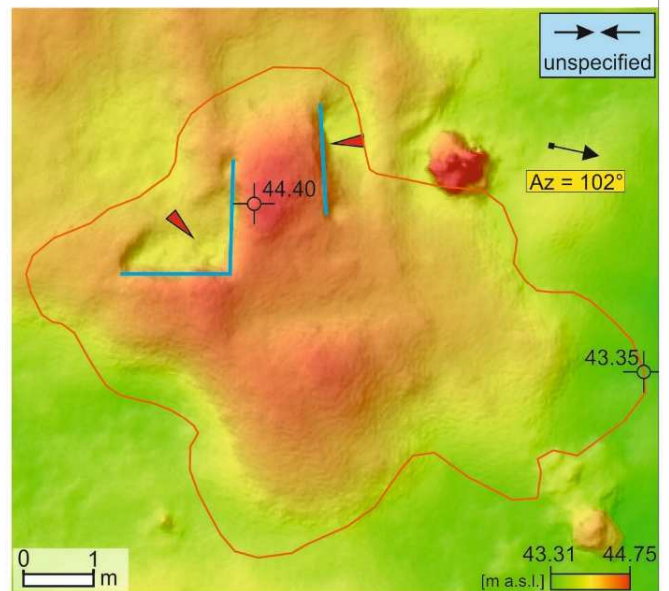

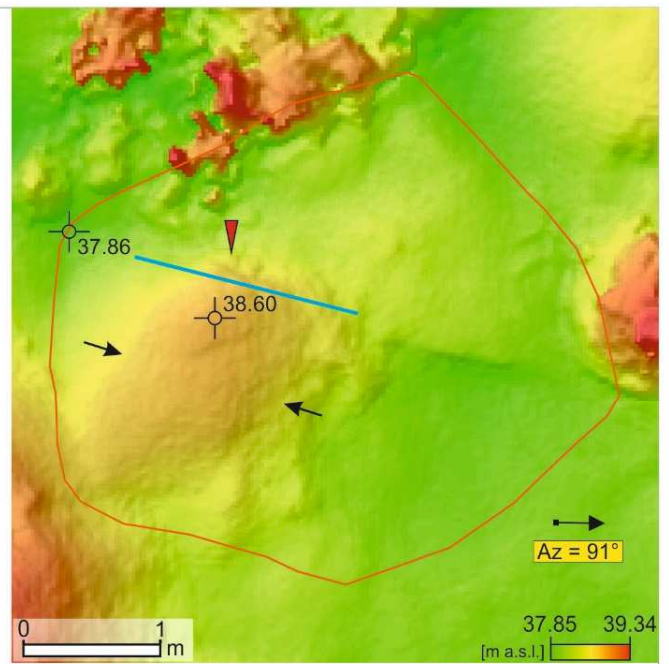

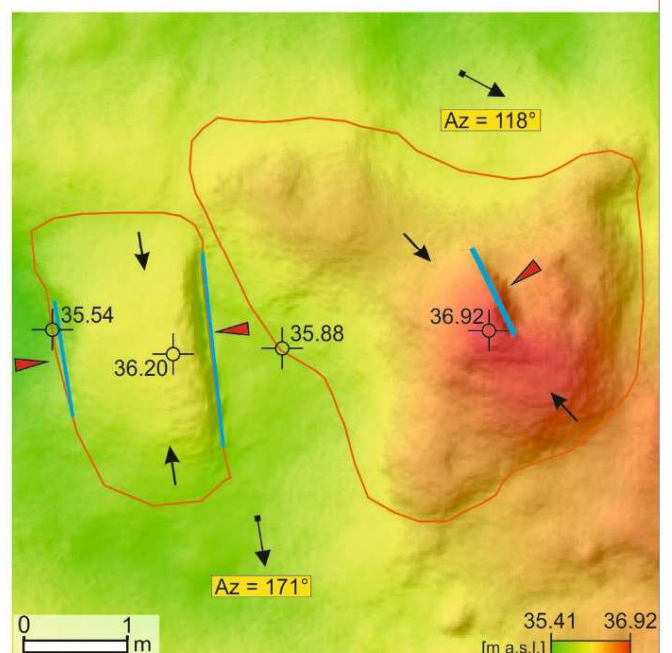

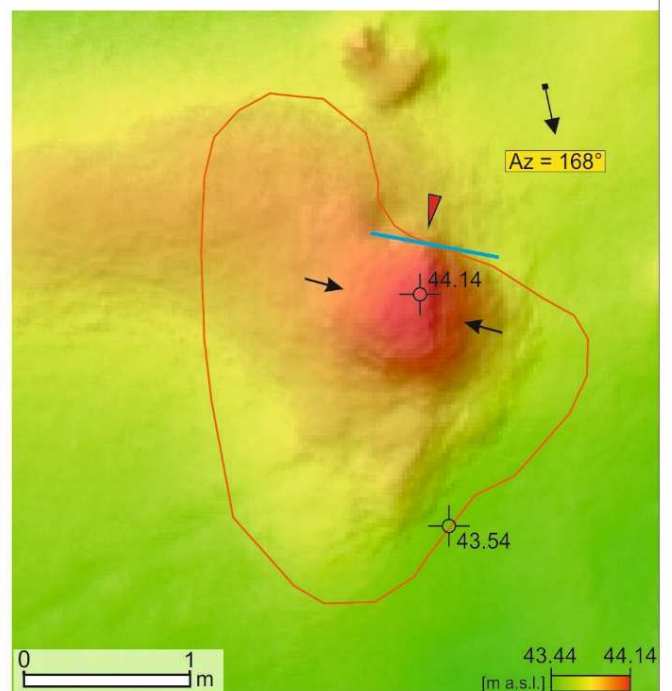

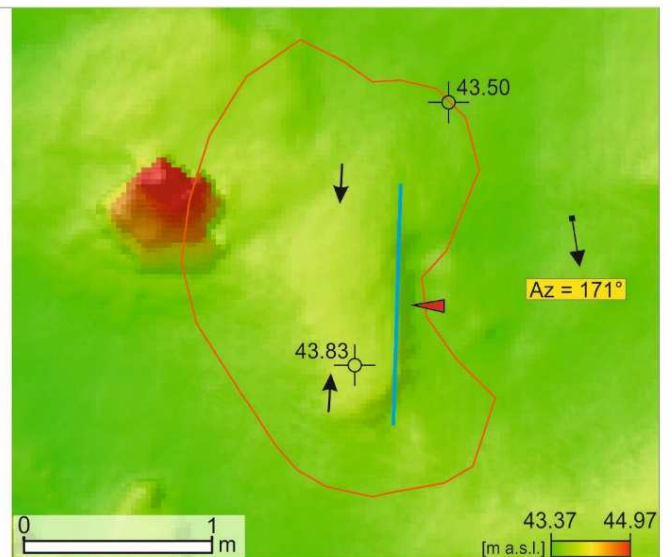

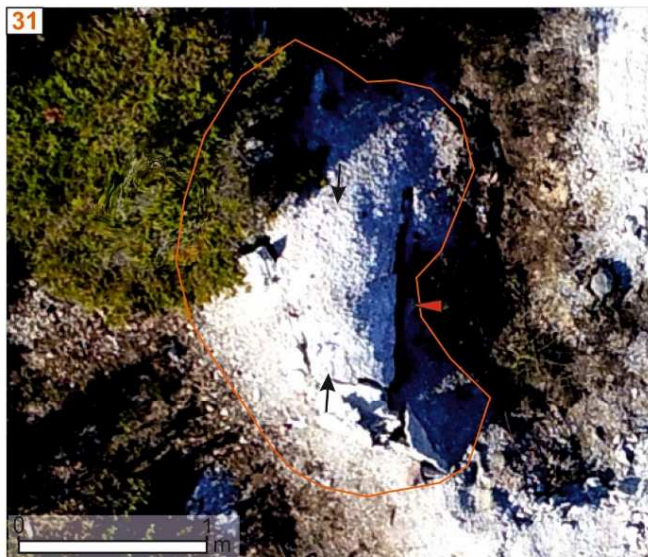

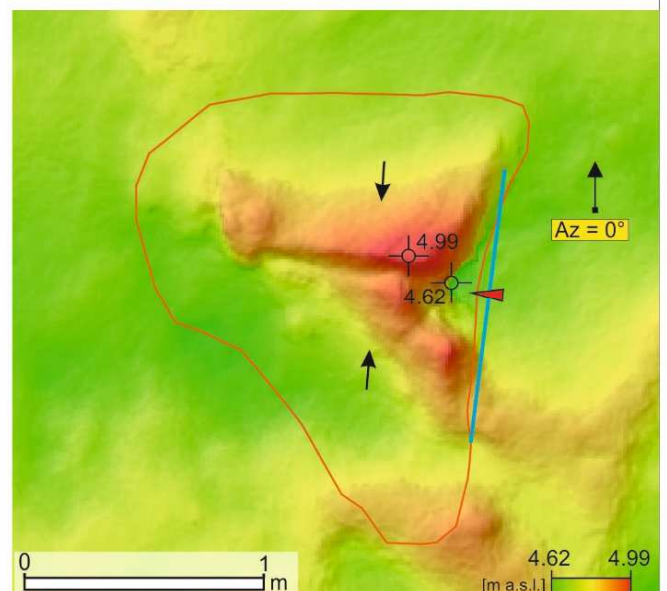

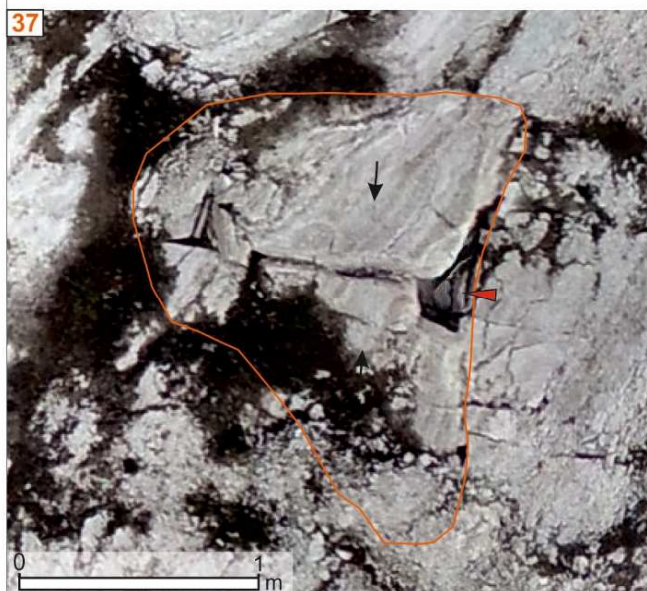

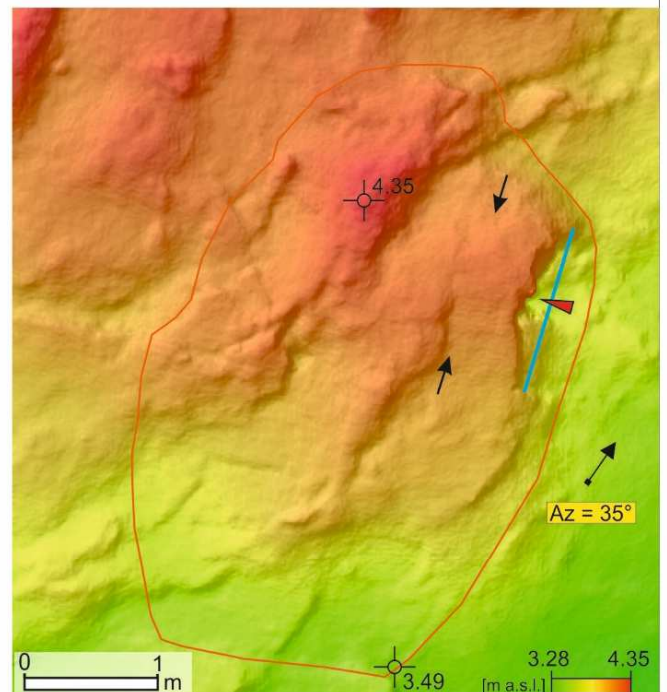

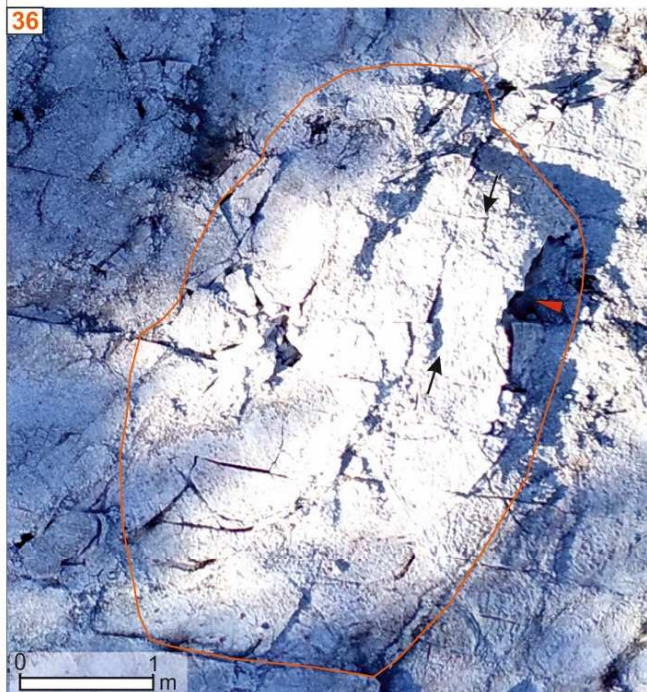

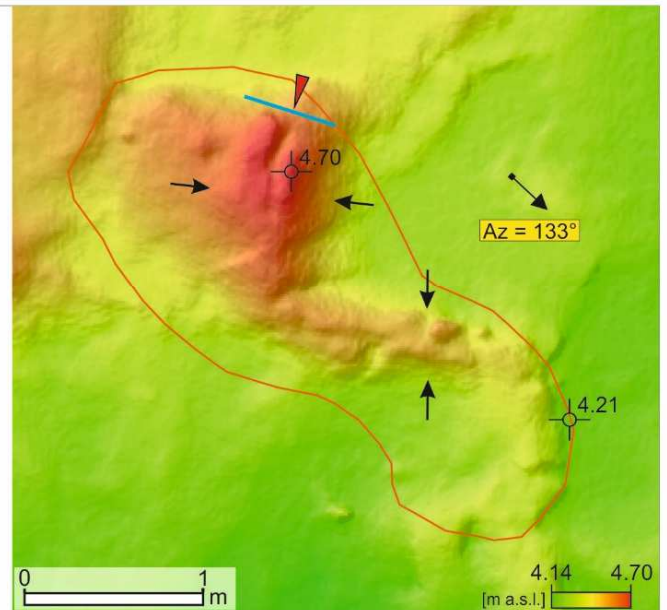

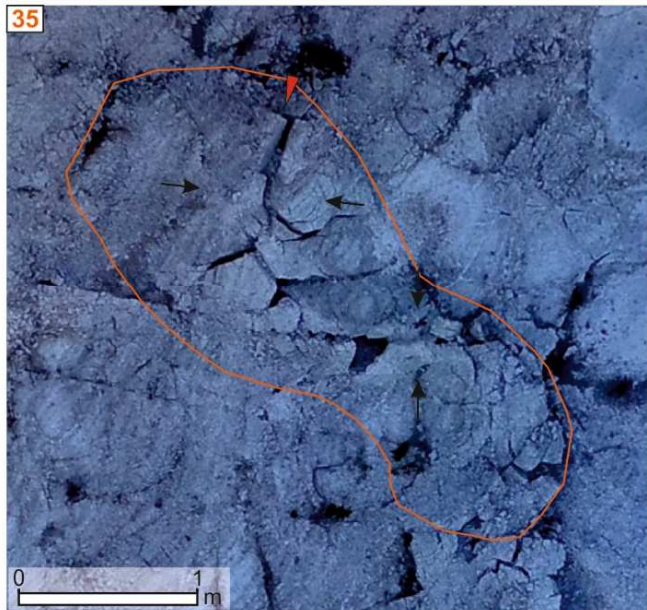

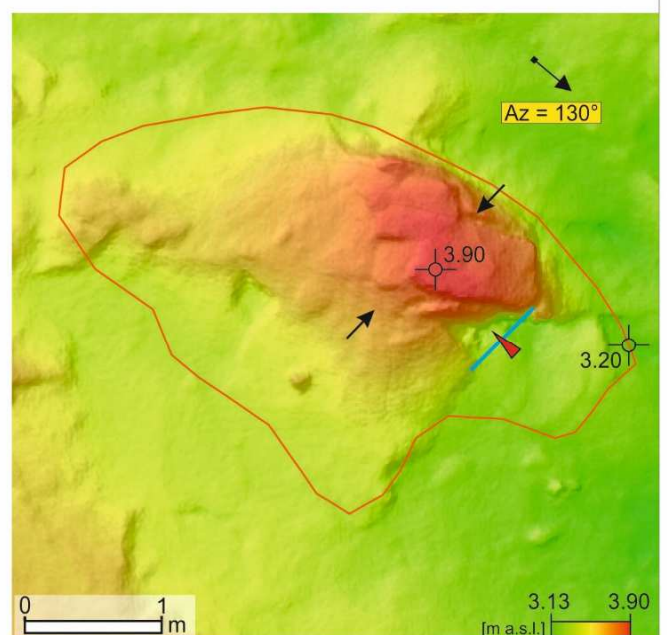

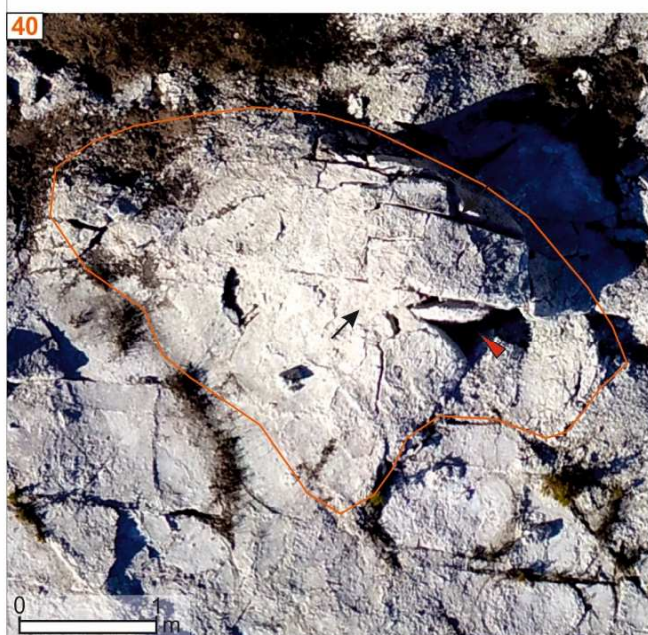

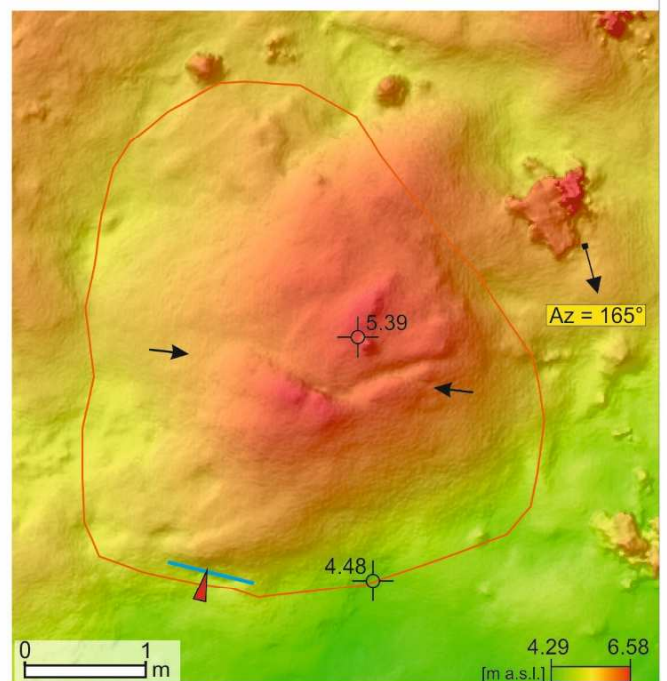

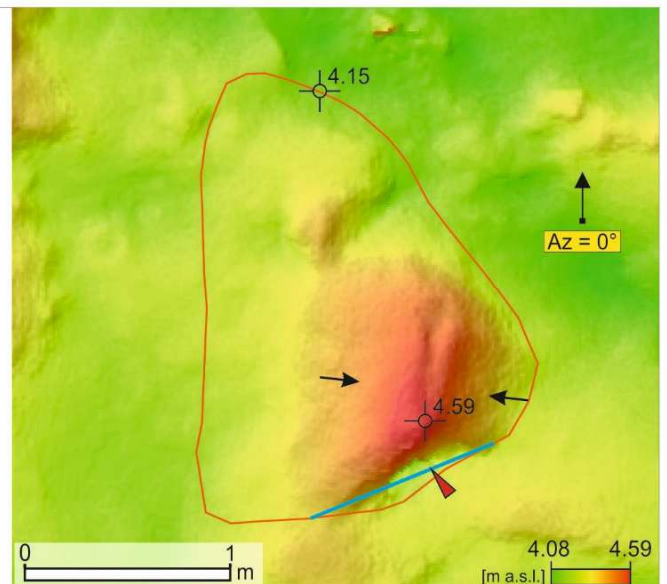

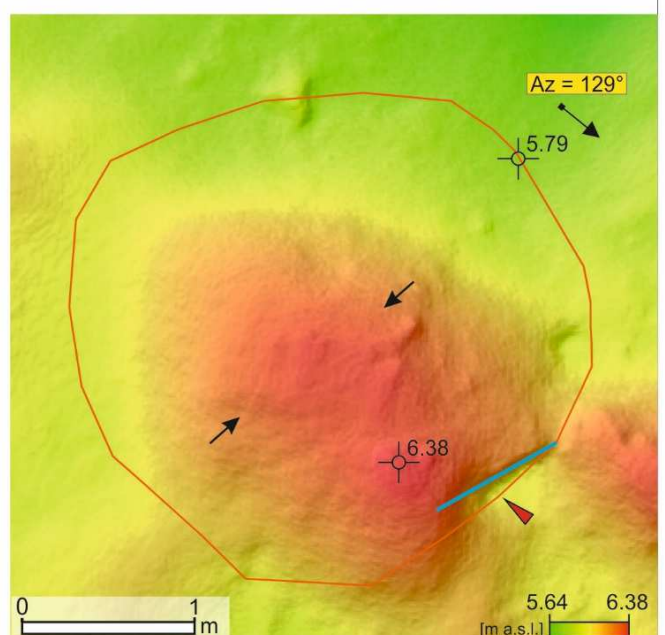

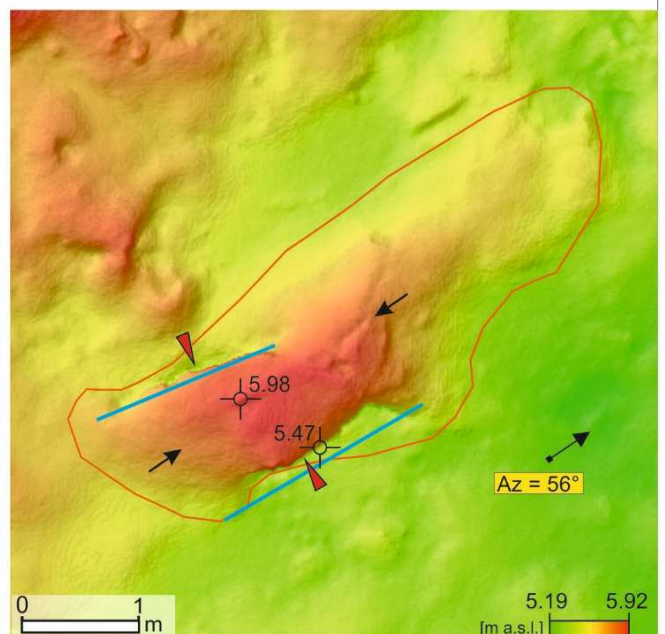

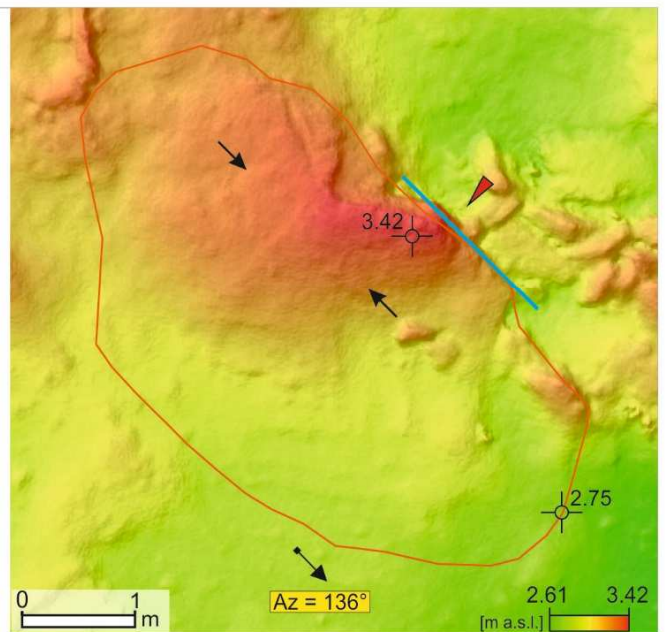

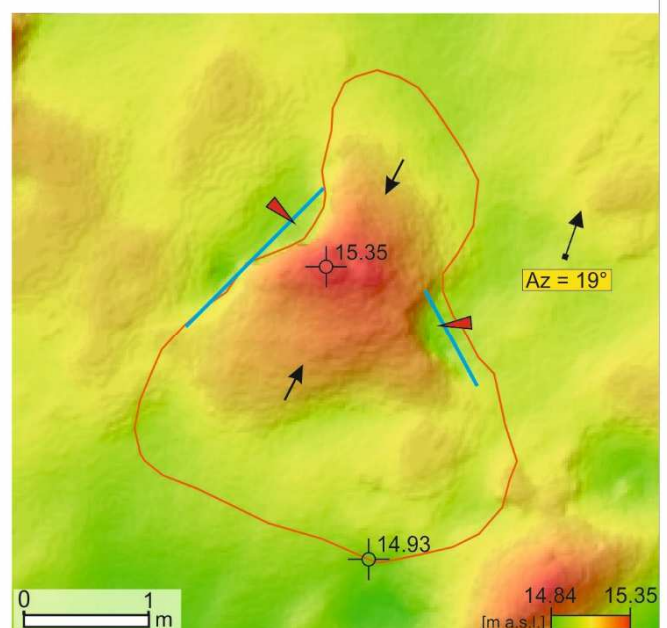

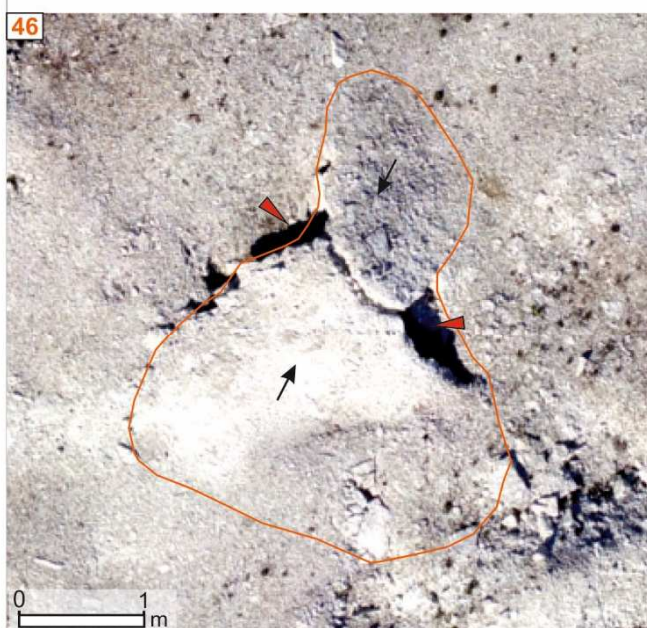

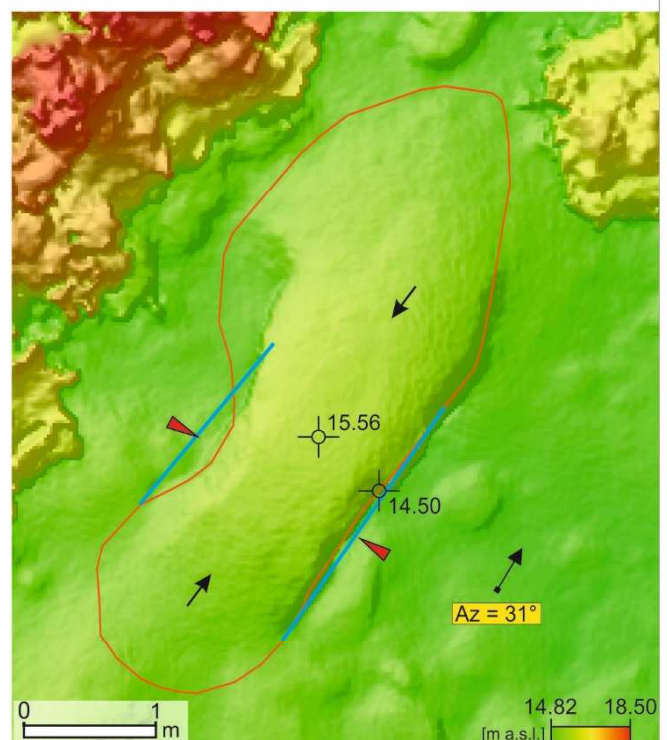

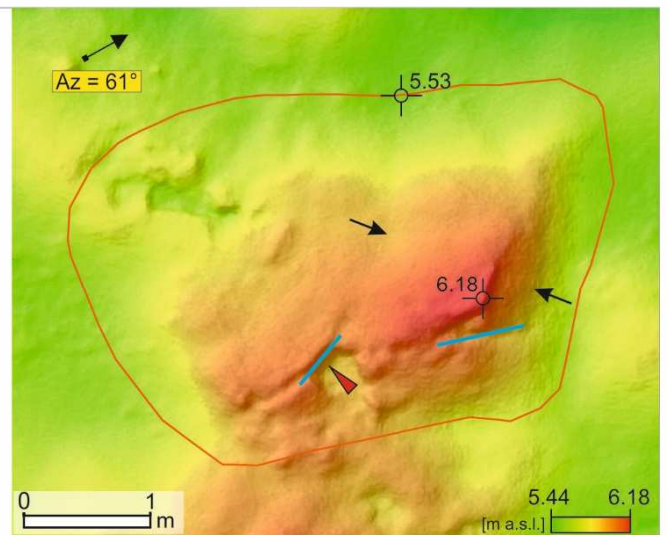

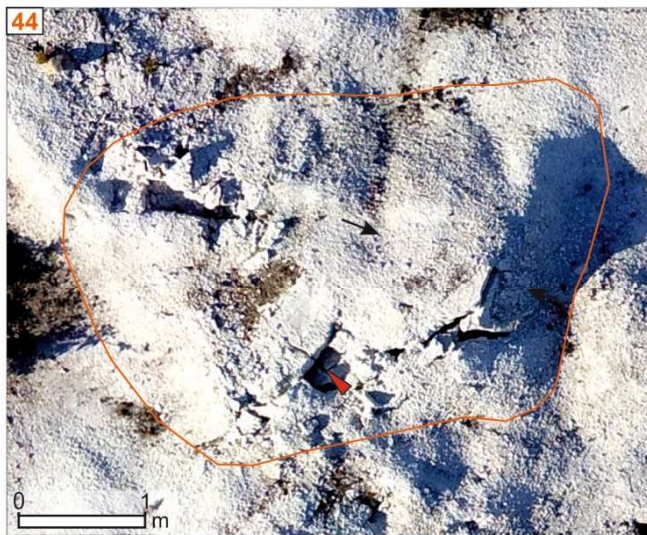

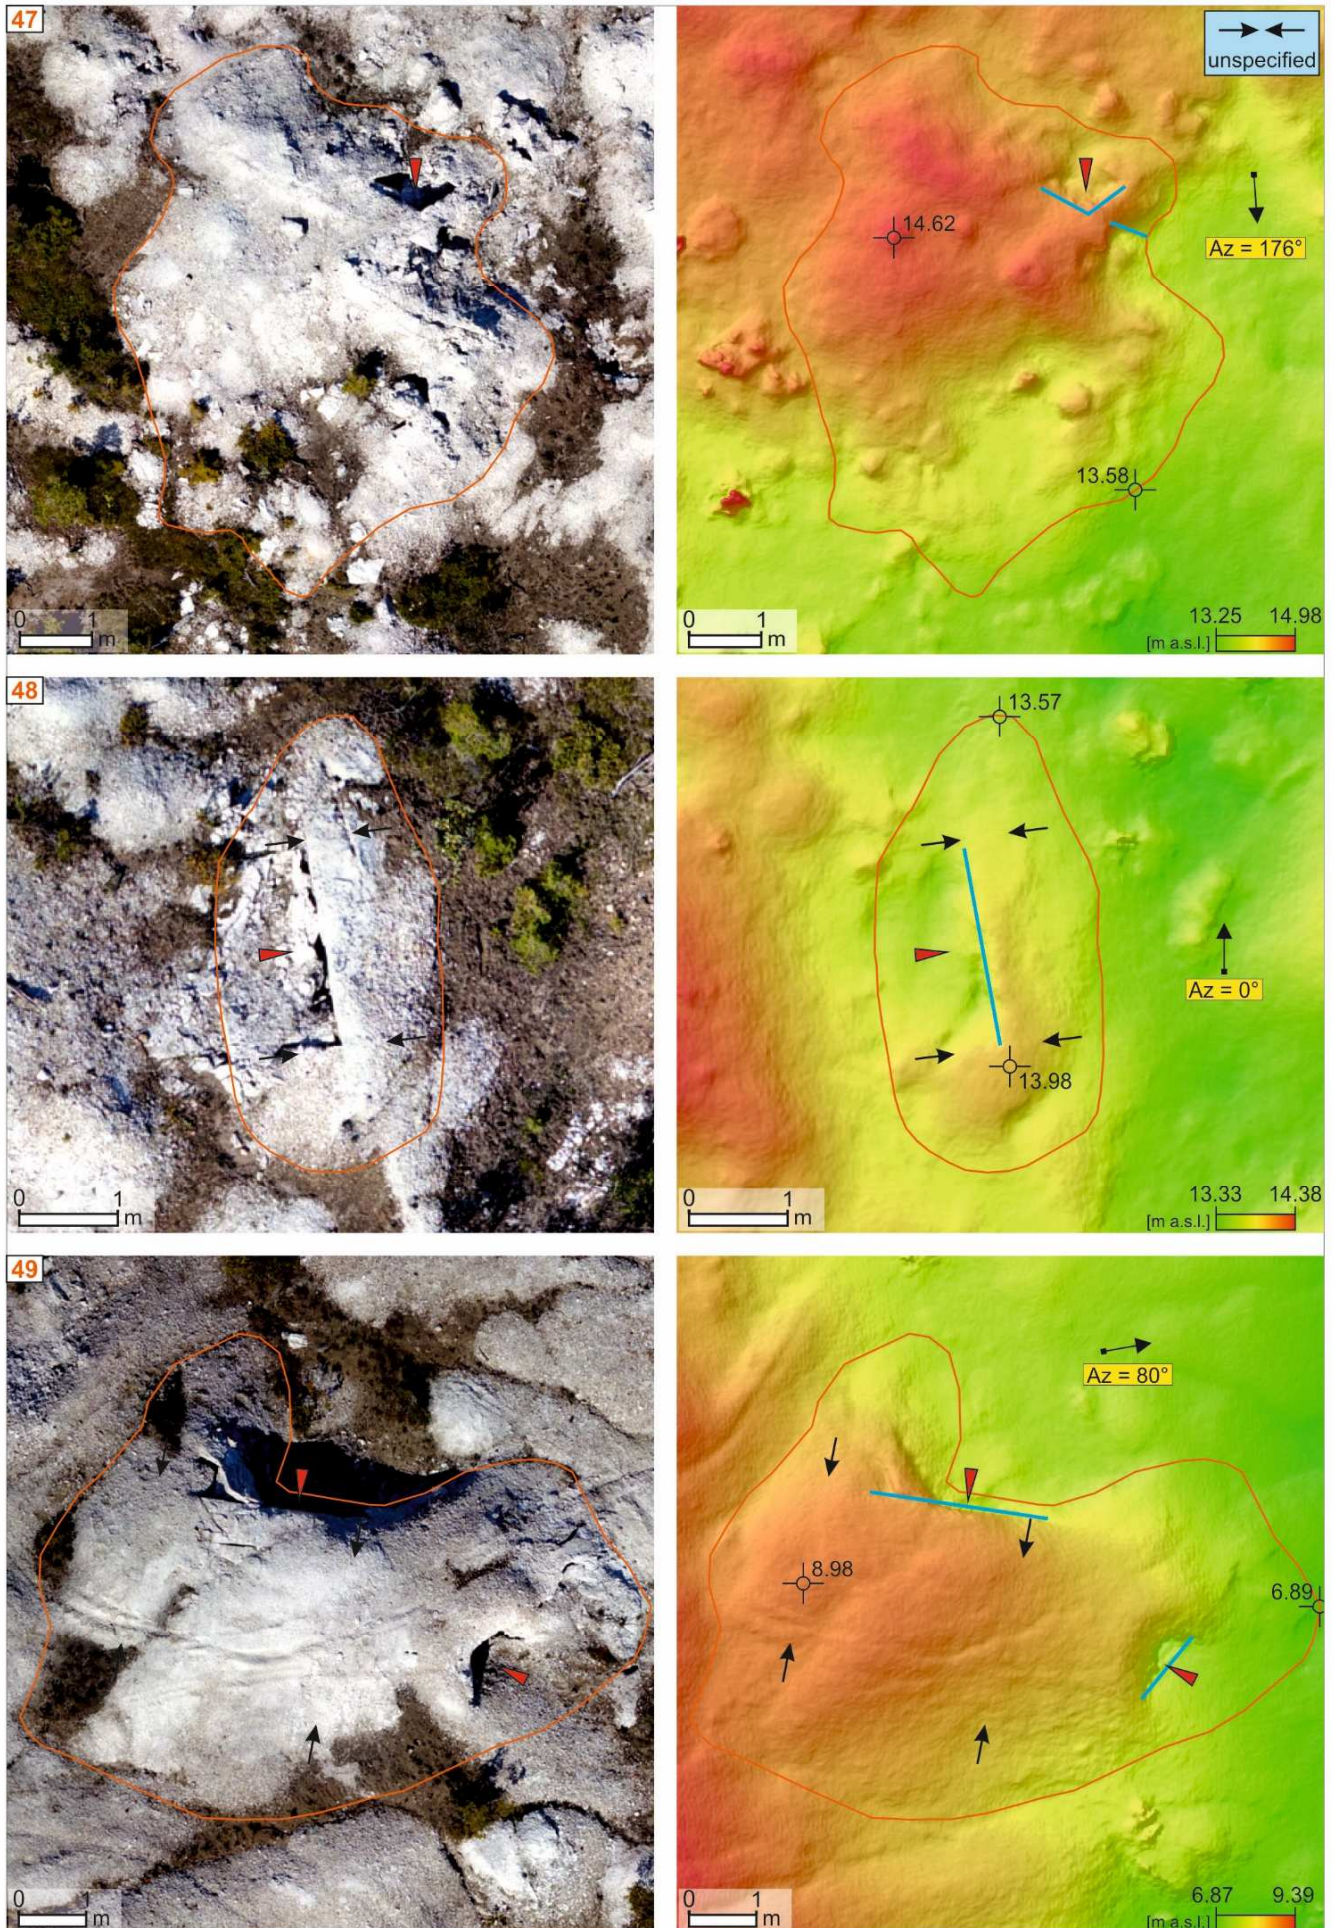

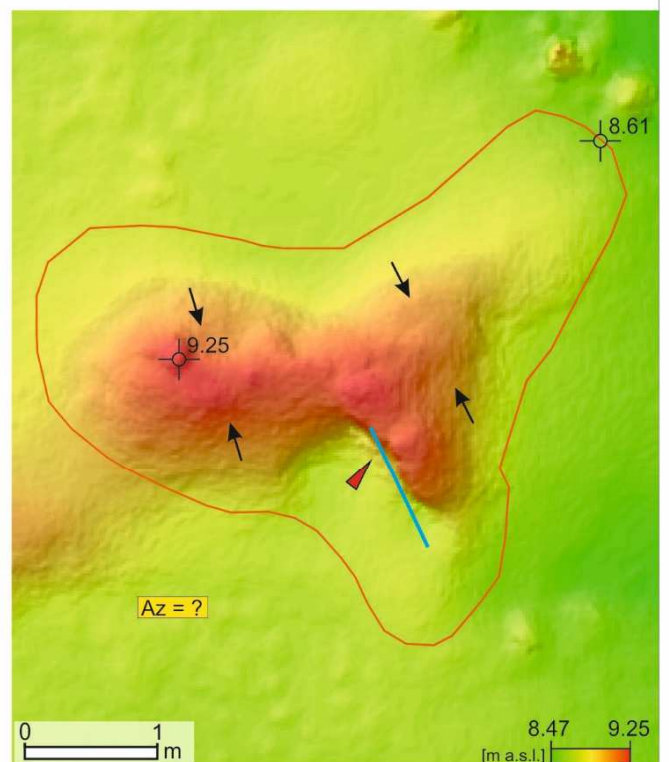

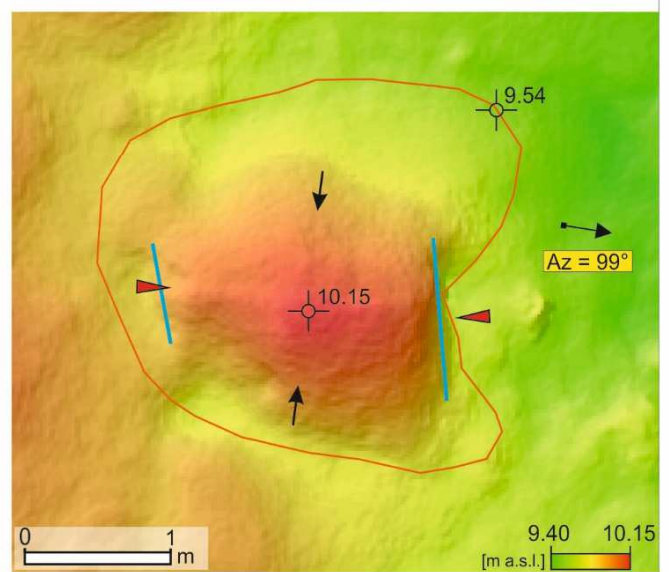

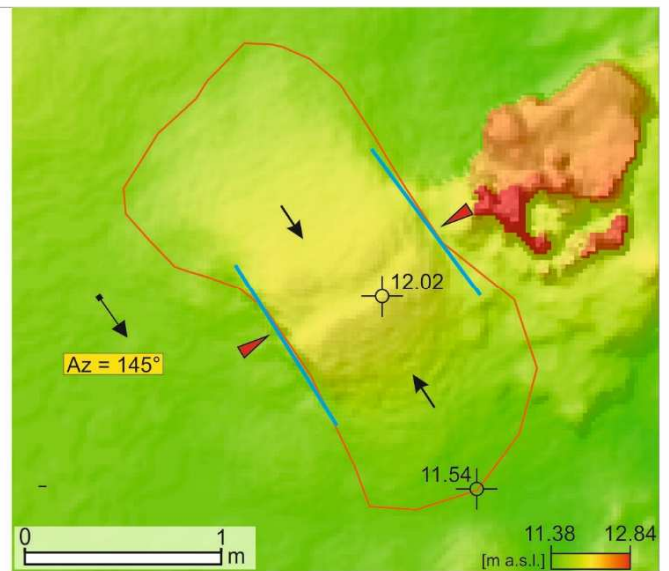

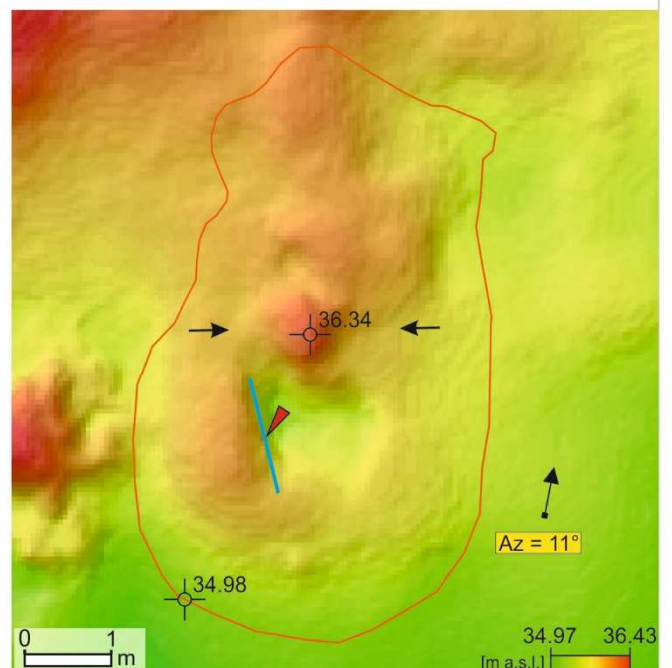

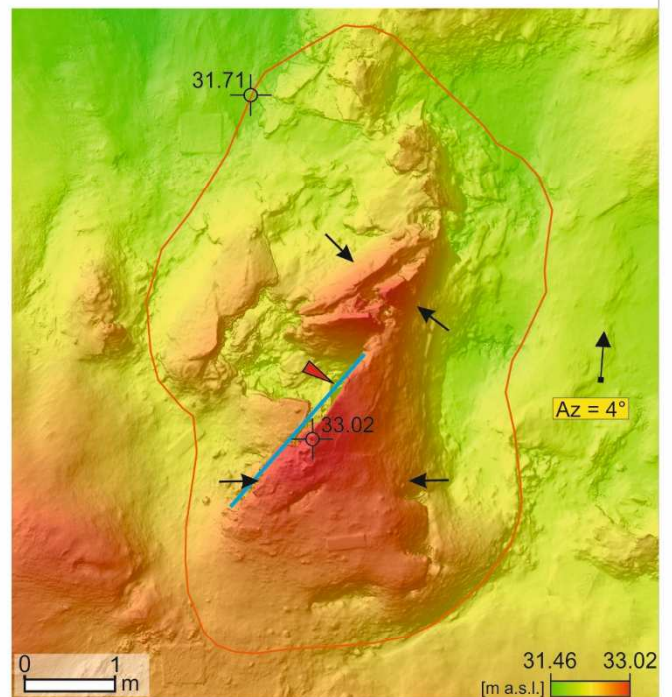

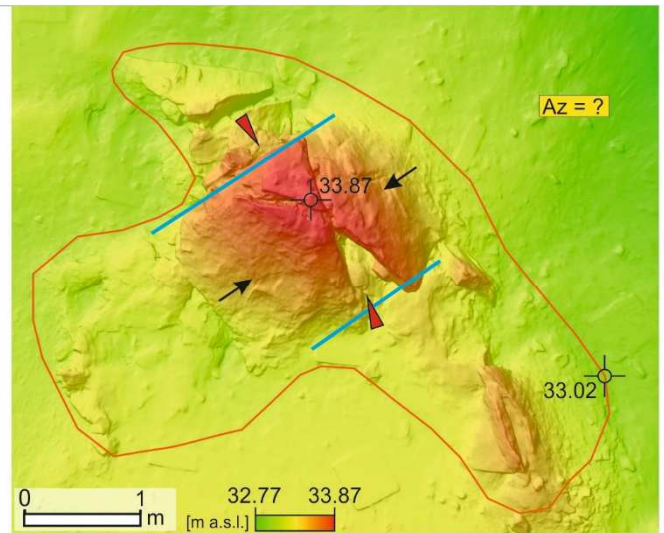

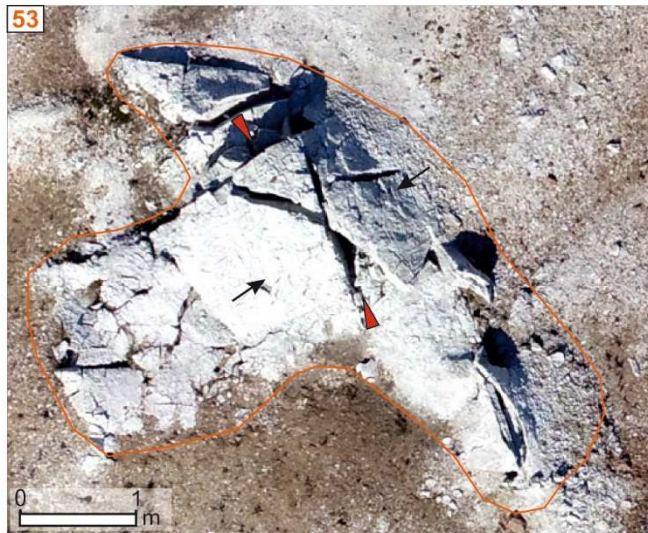

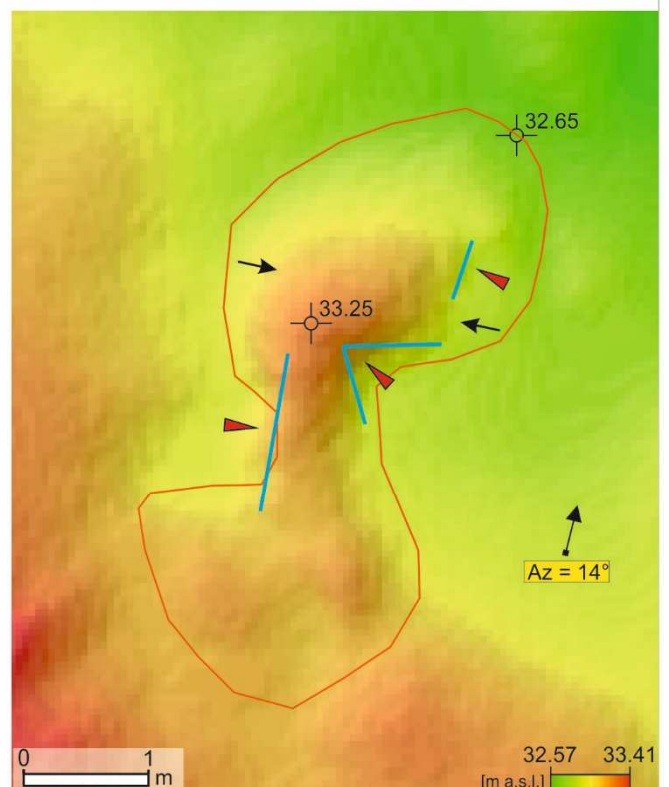

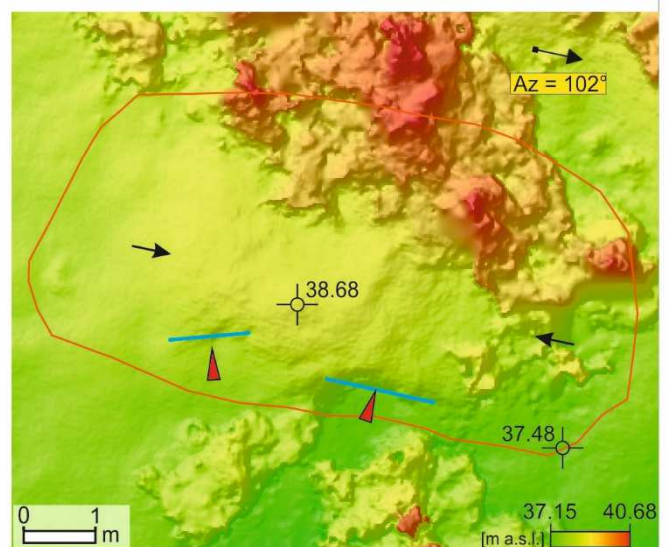

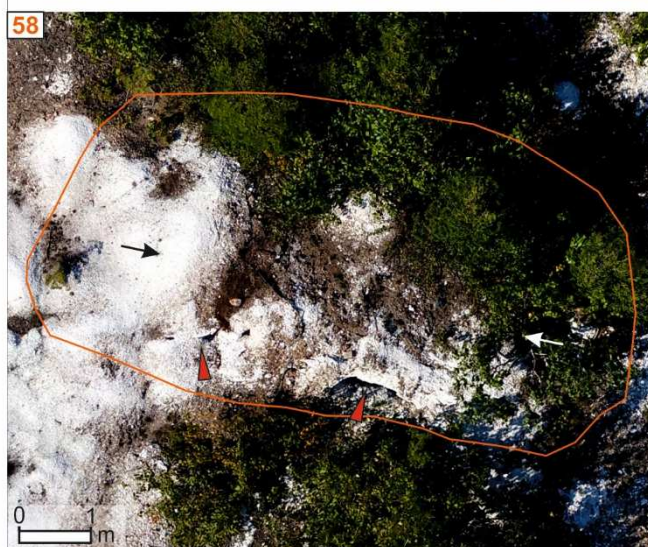

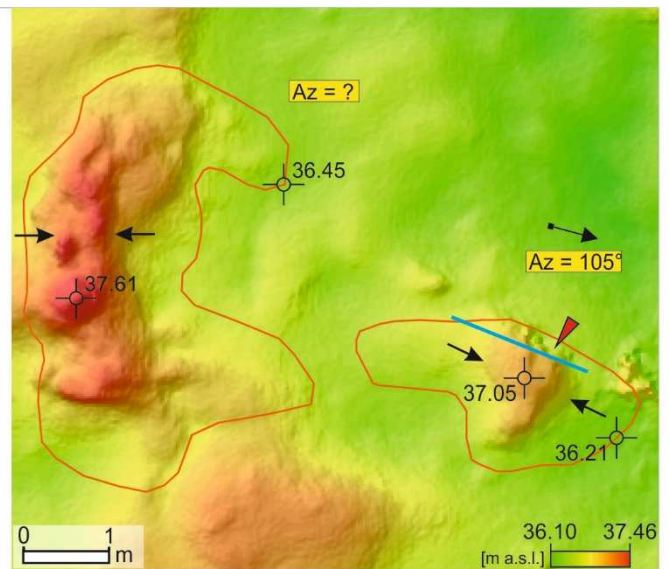

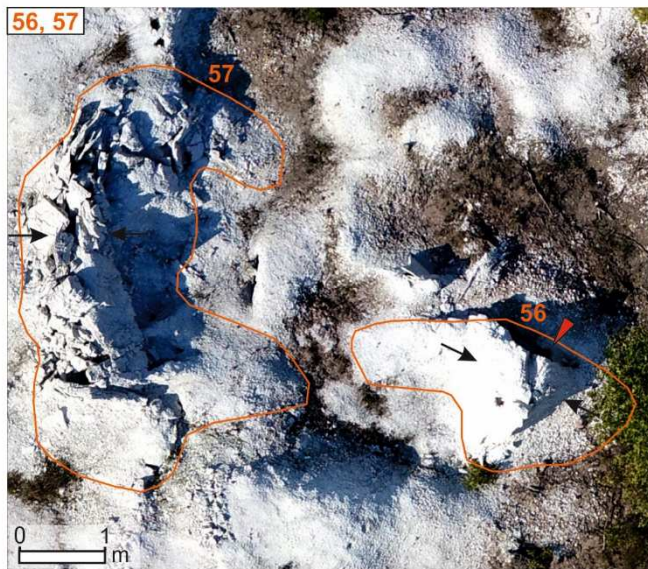

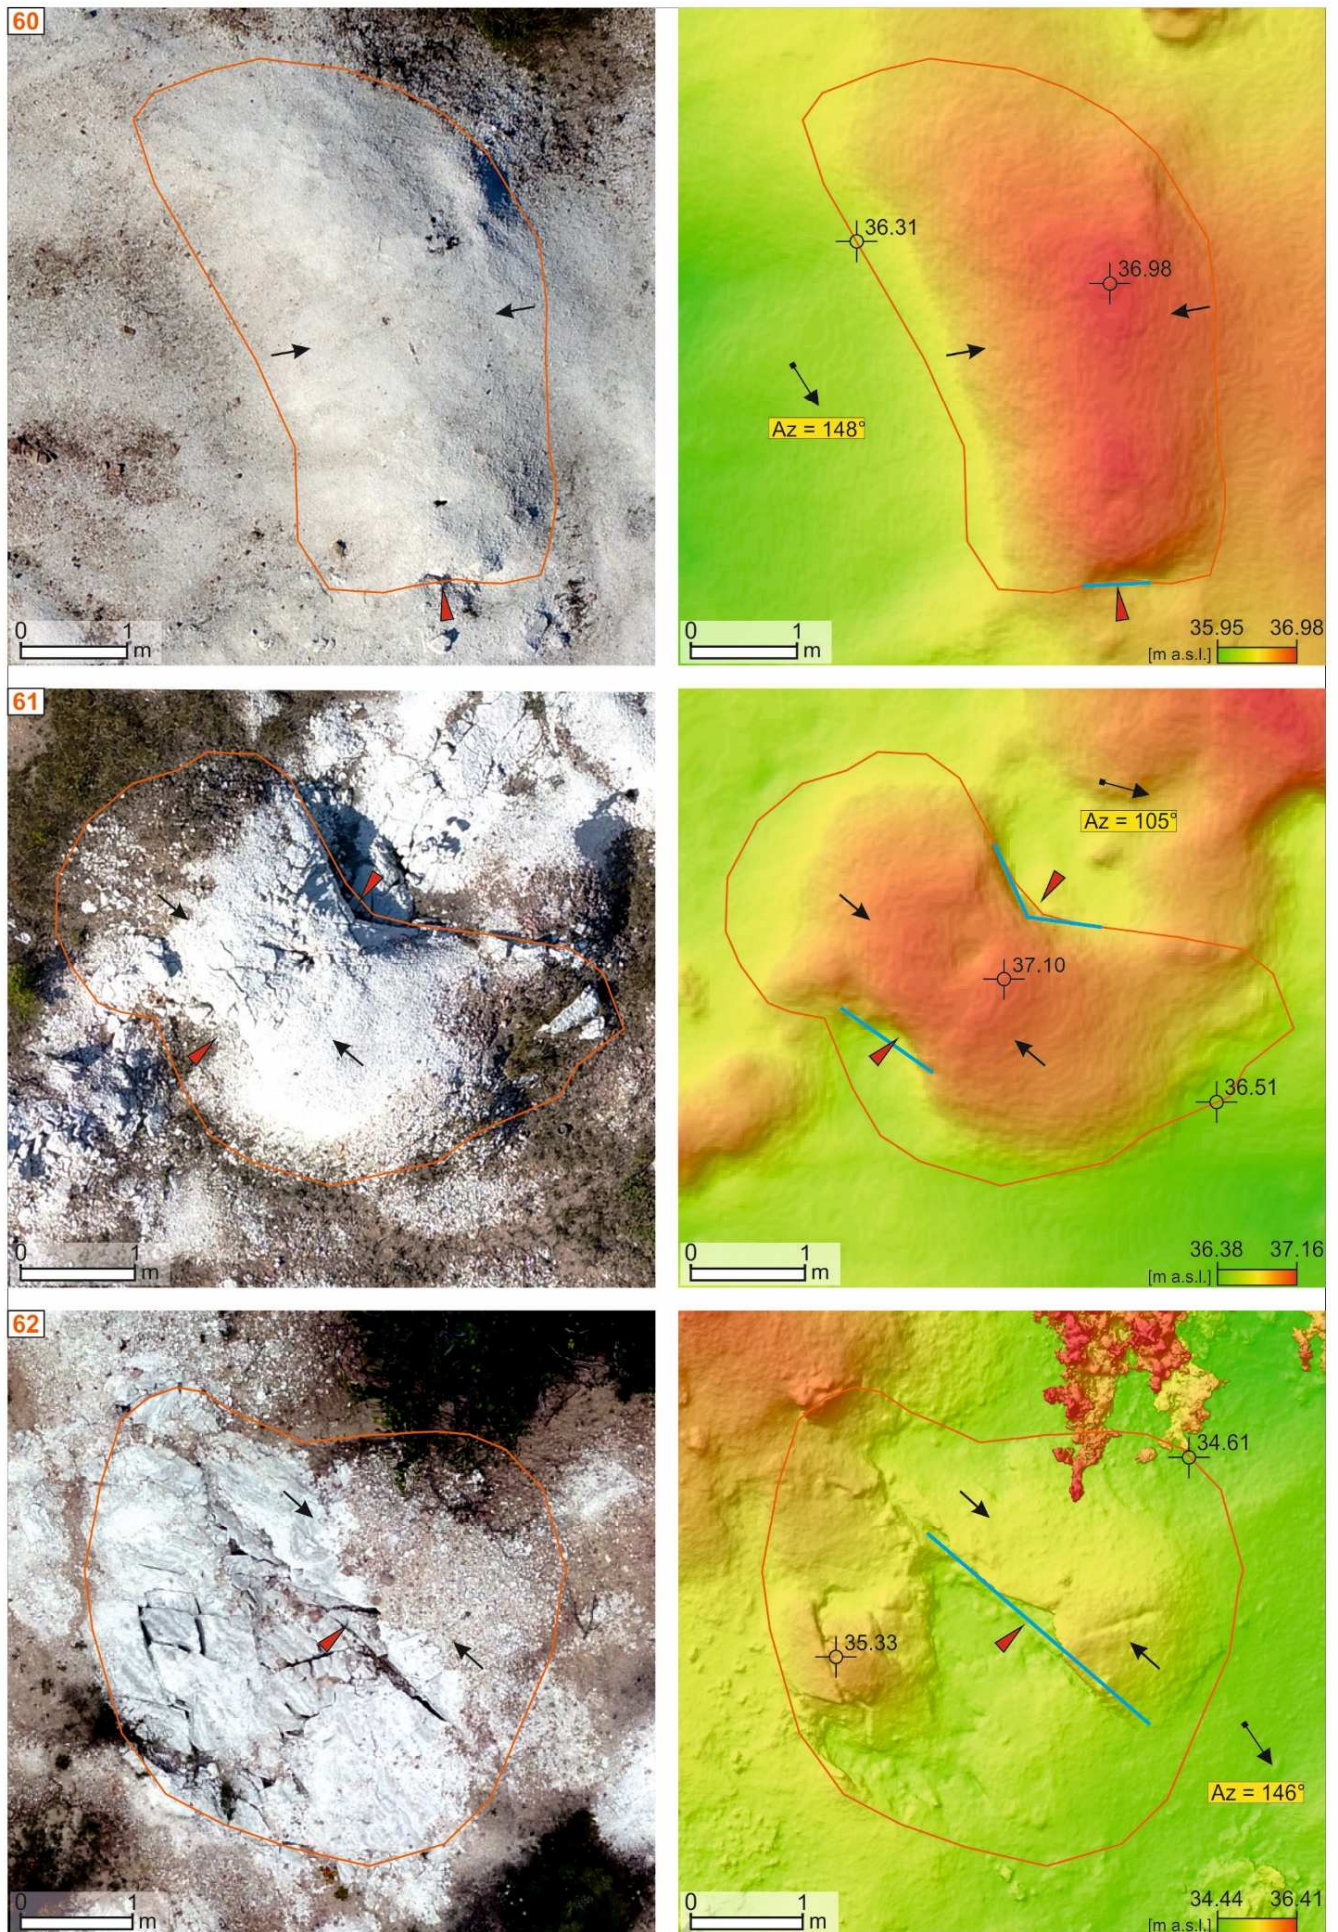

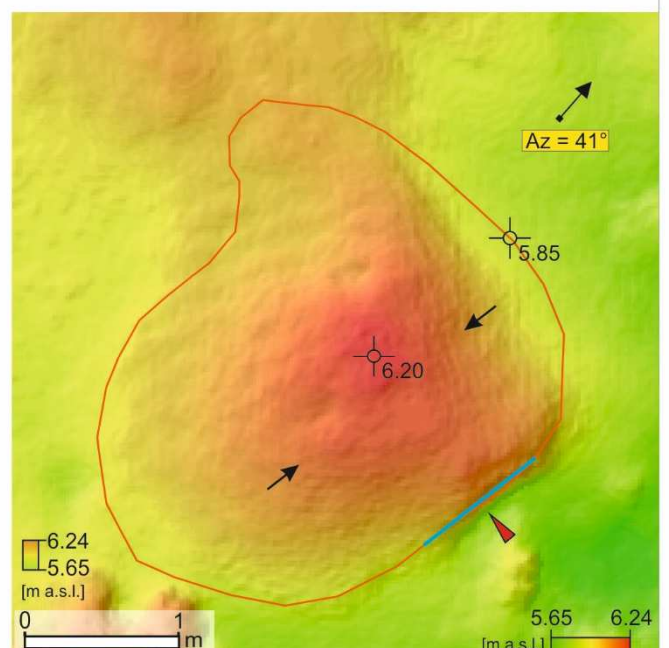

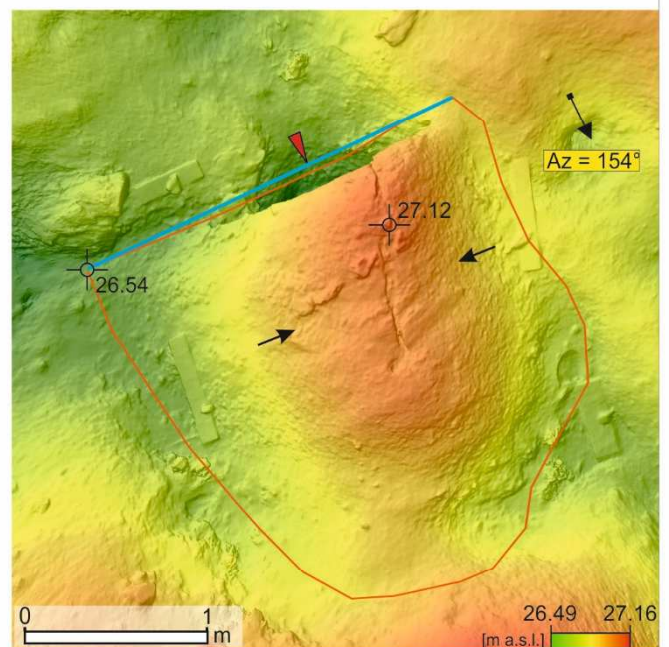

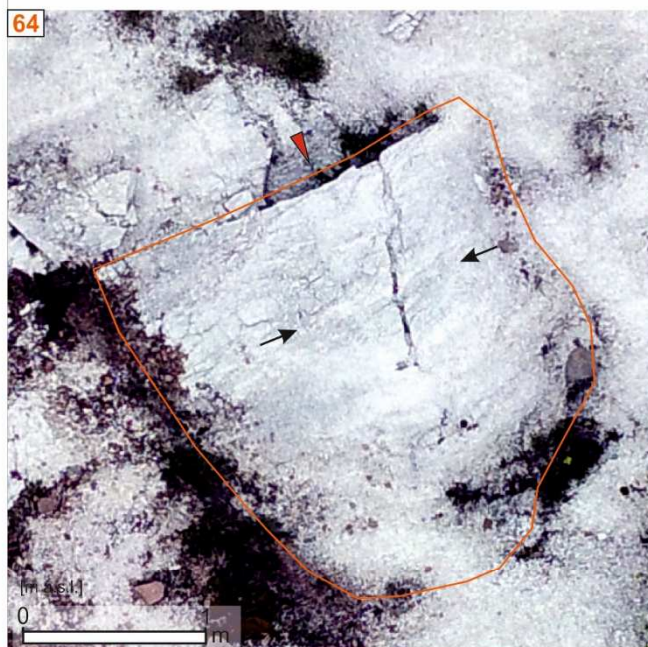

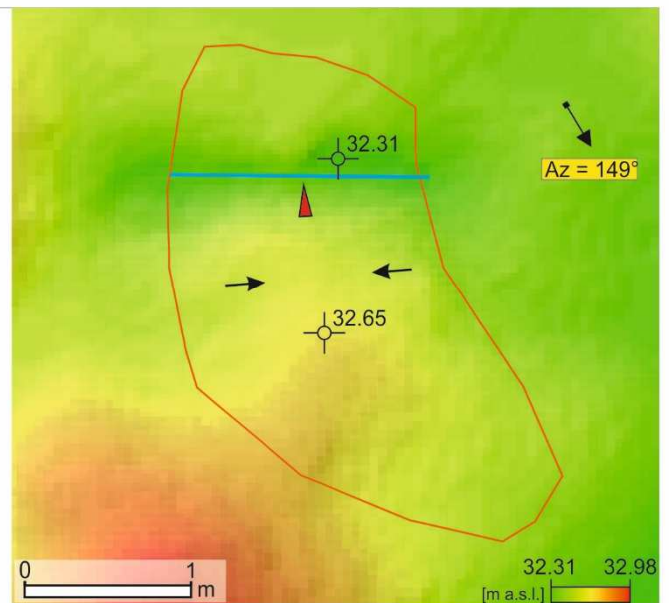

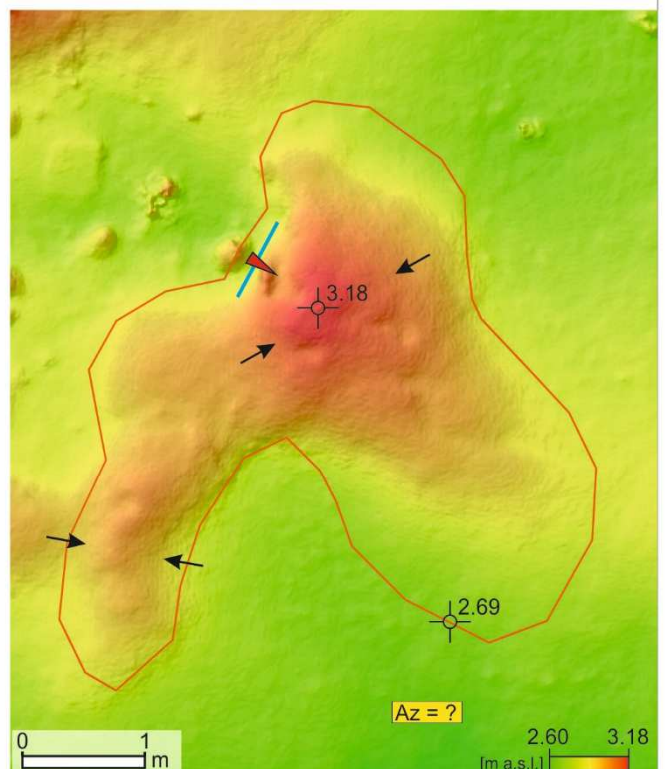

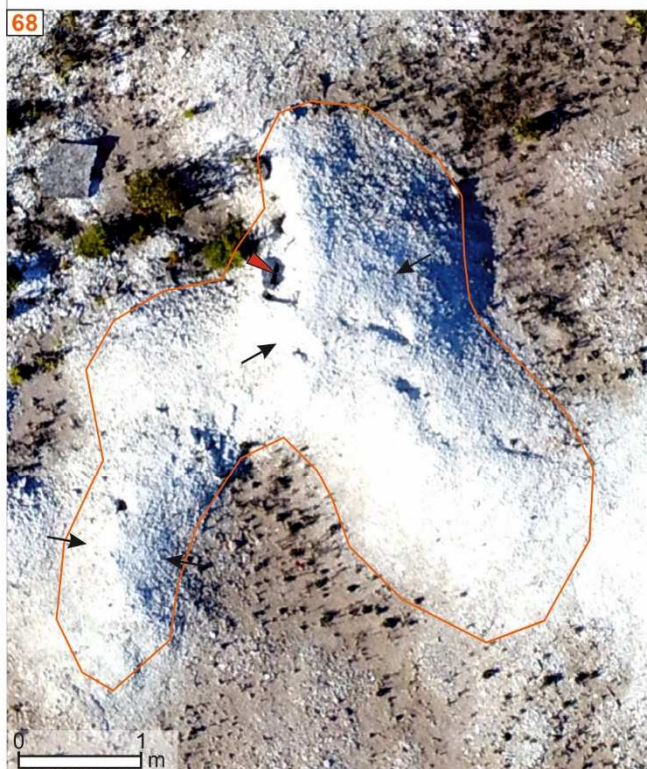

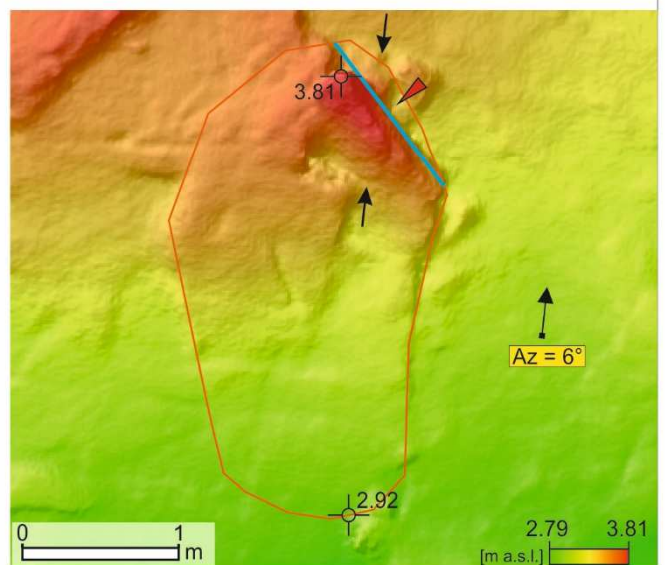

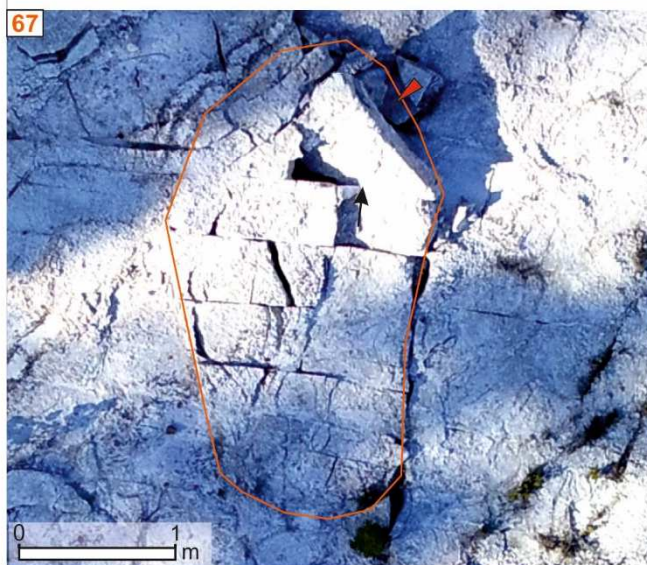

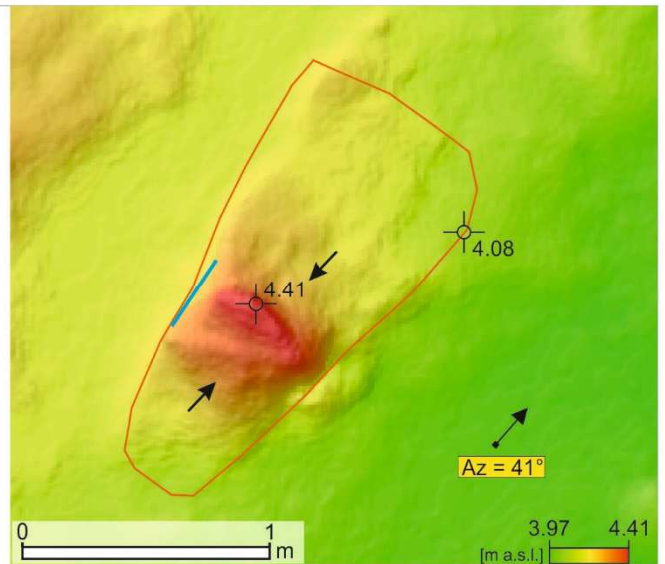

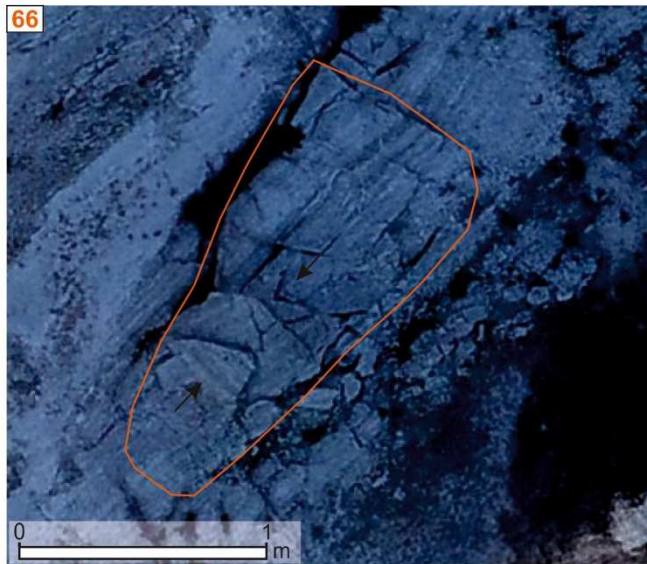

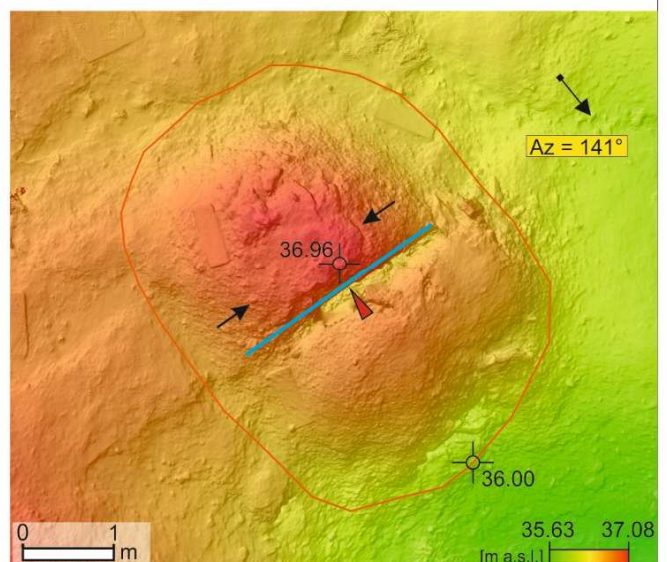

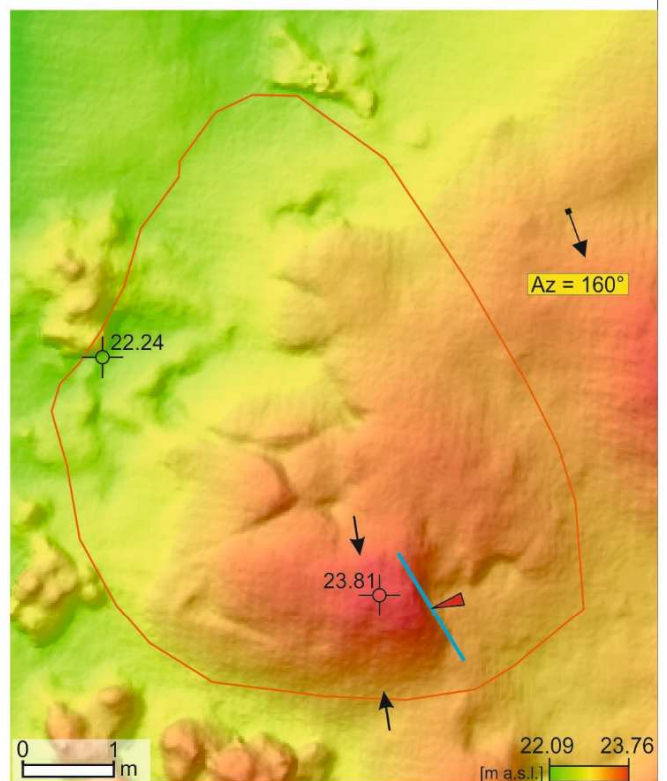

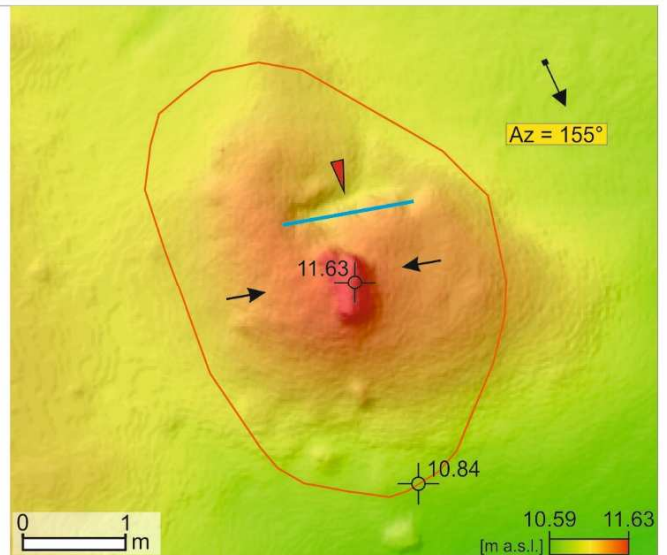

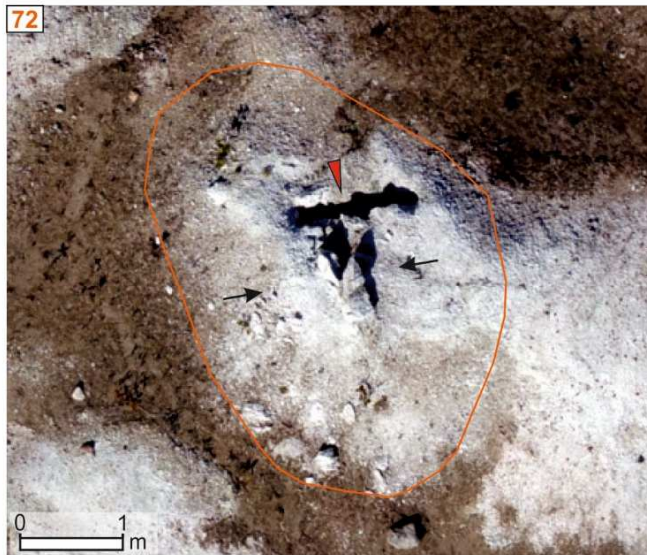

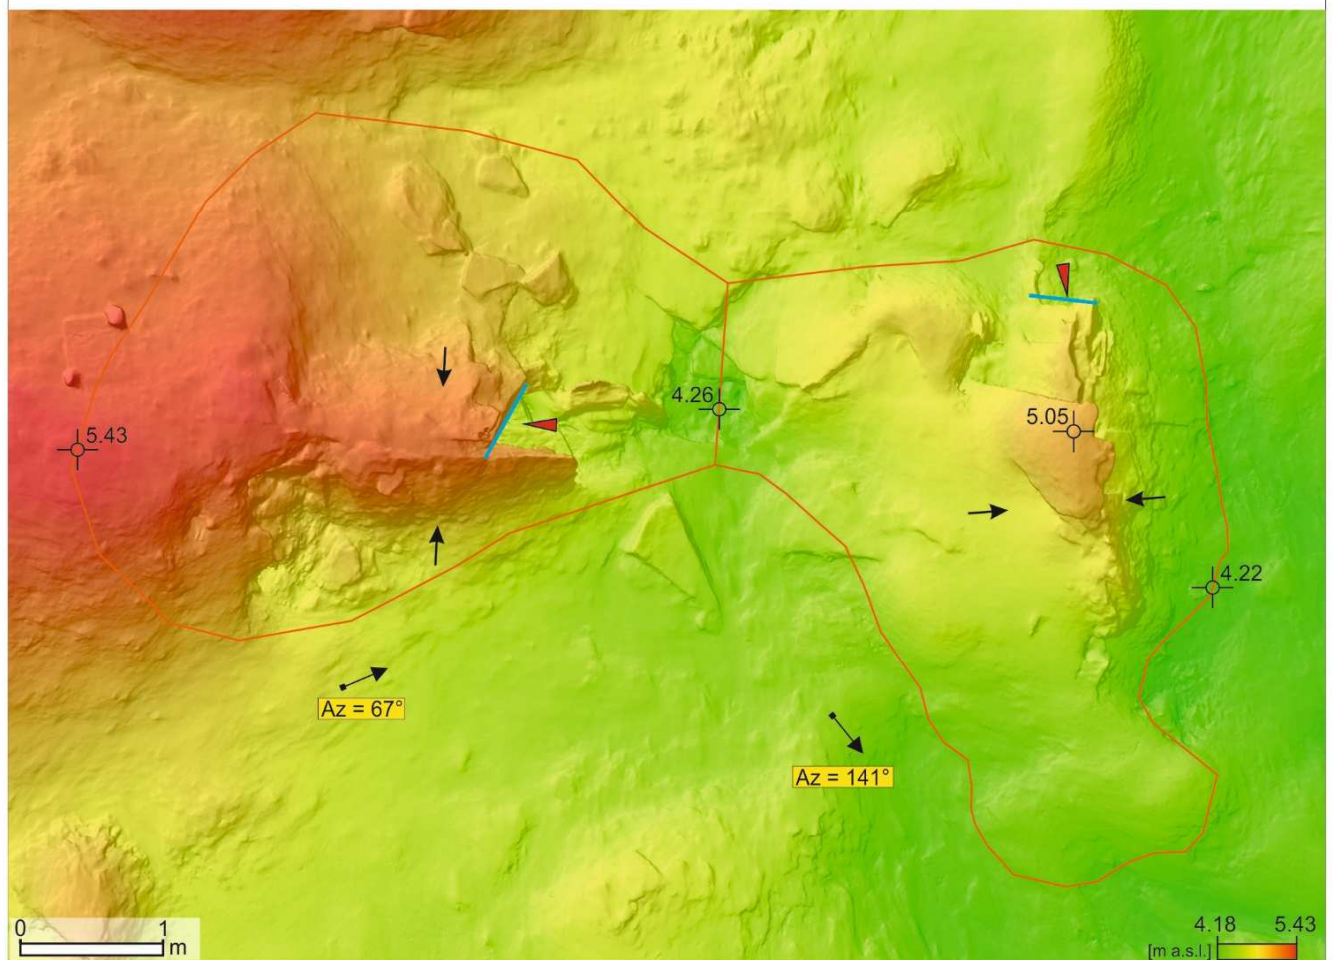

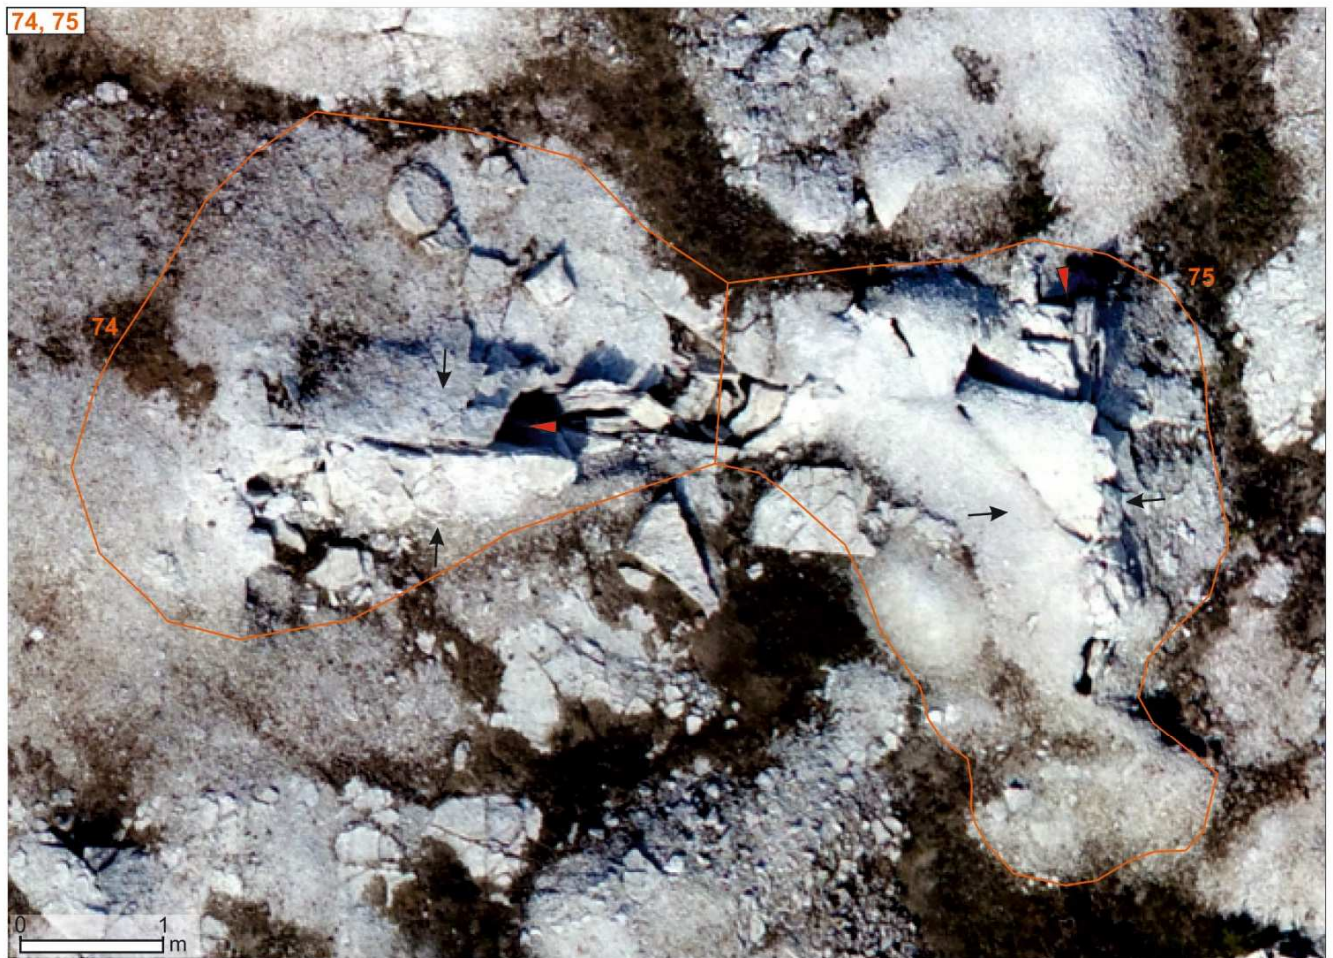

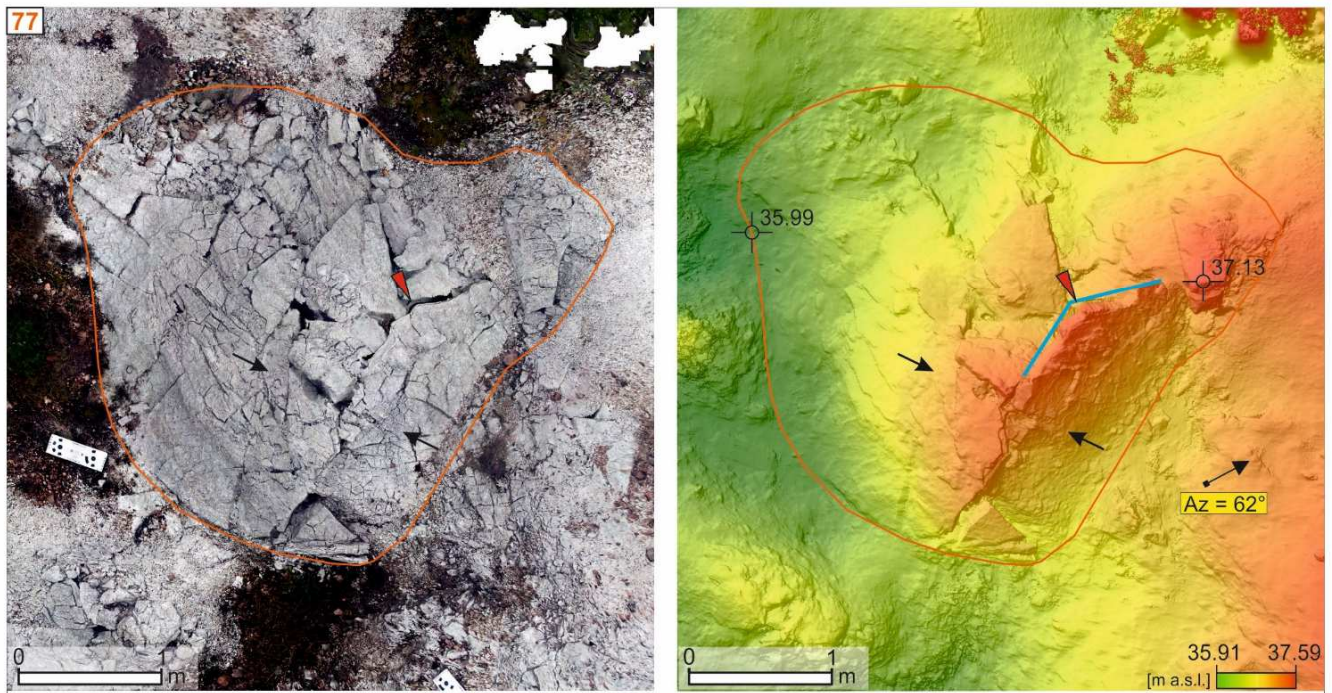

Figure S3

Location of hydration landforms on the basemap of satellite image (source: ArcGIS program) with characteristic of their sizes.

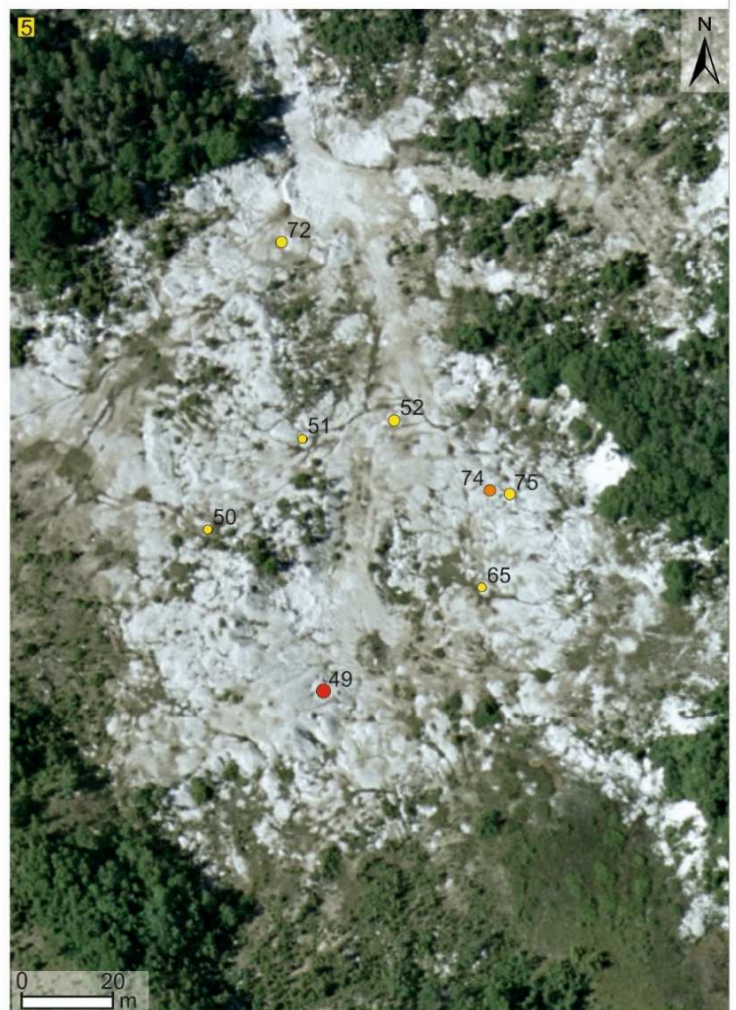

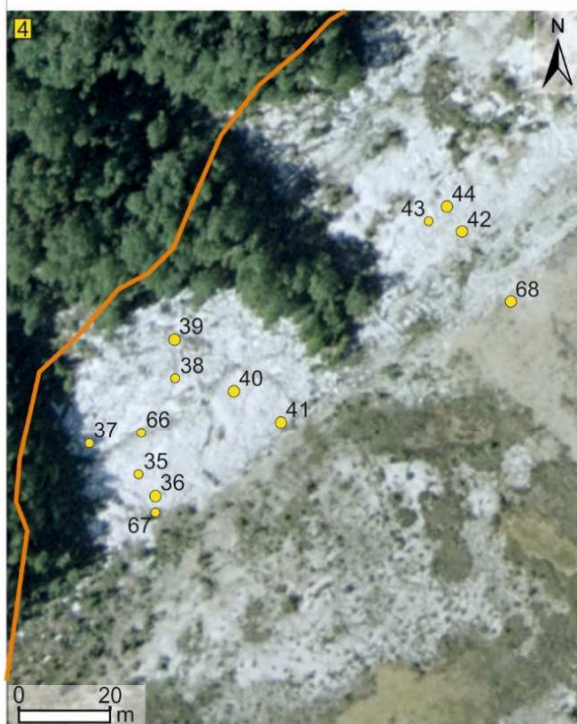

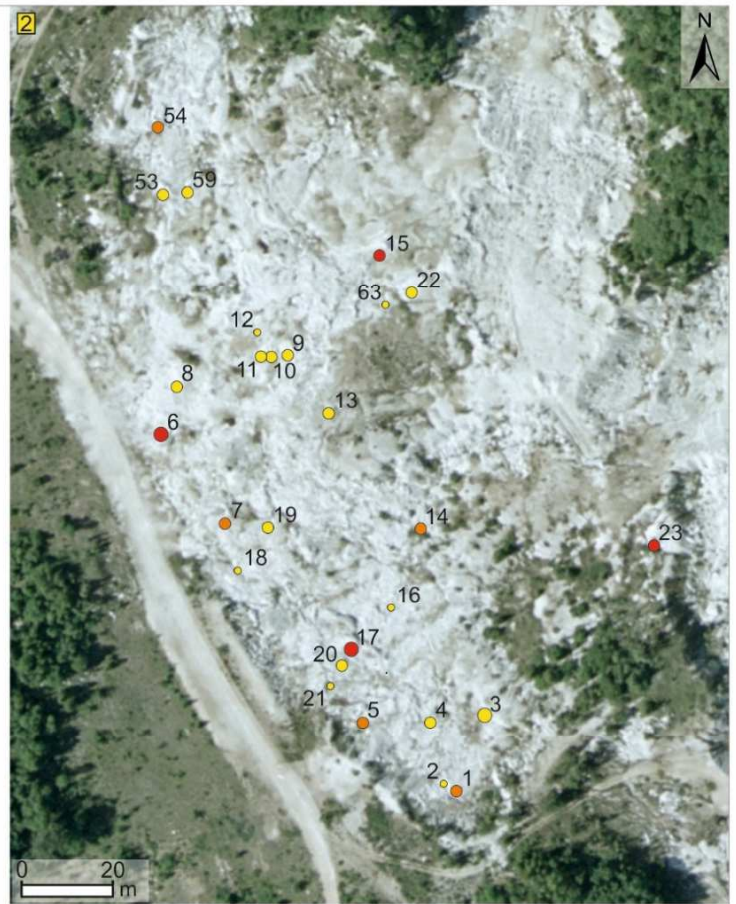

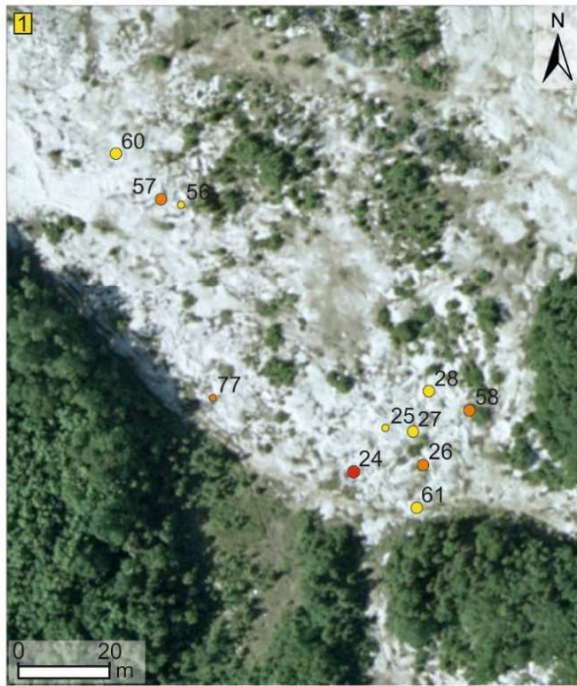

Figure S4
Location of hydration landforms with measured thickness of the detached layer
on the basemap of satellite image (source: ArcGIS program).

Figure S5

Frequency distribution diagrams of morphometric parameters characterising hydration landforms, for intervals left-closed and right-open.

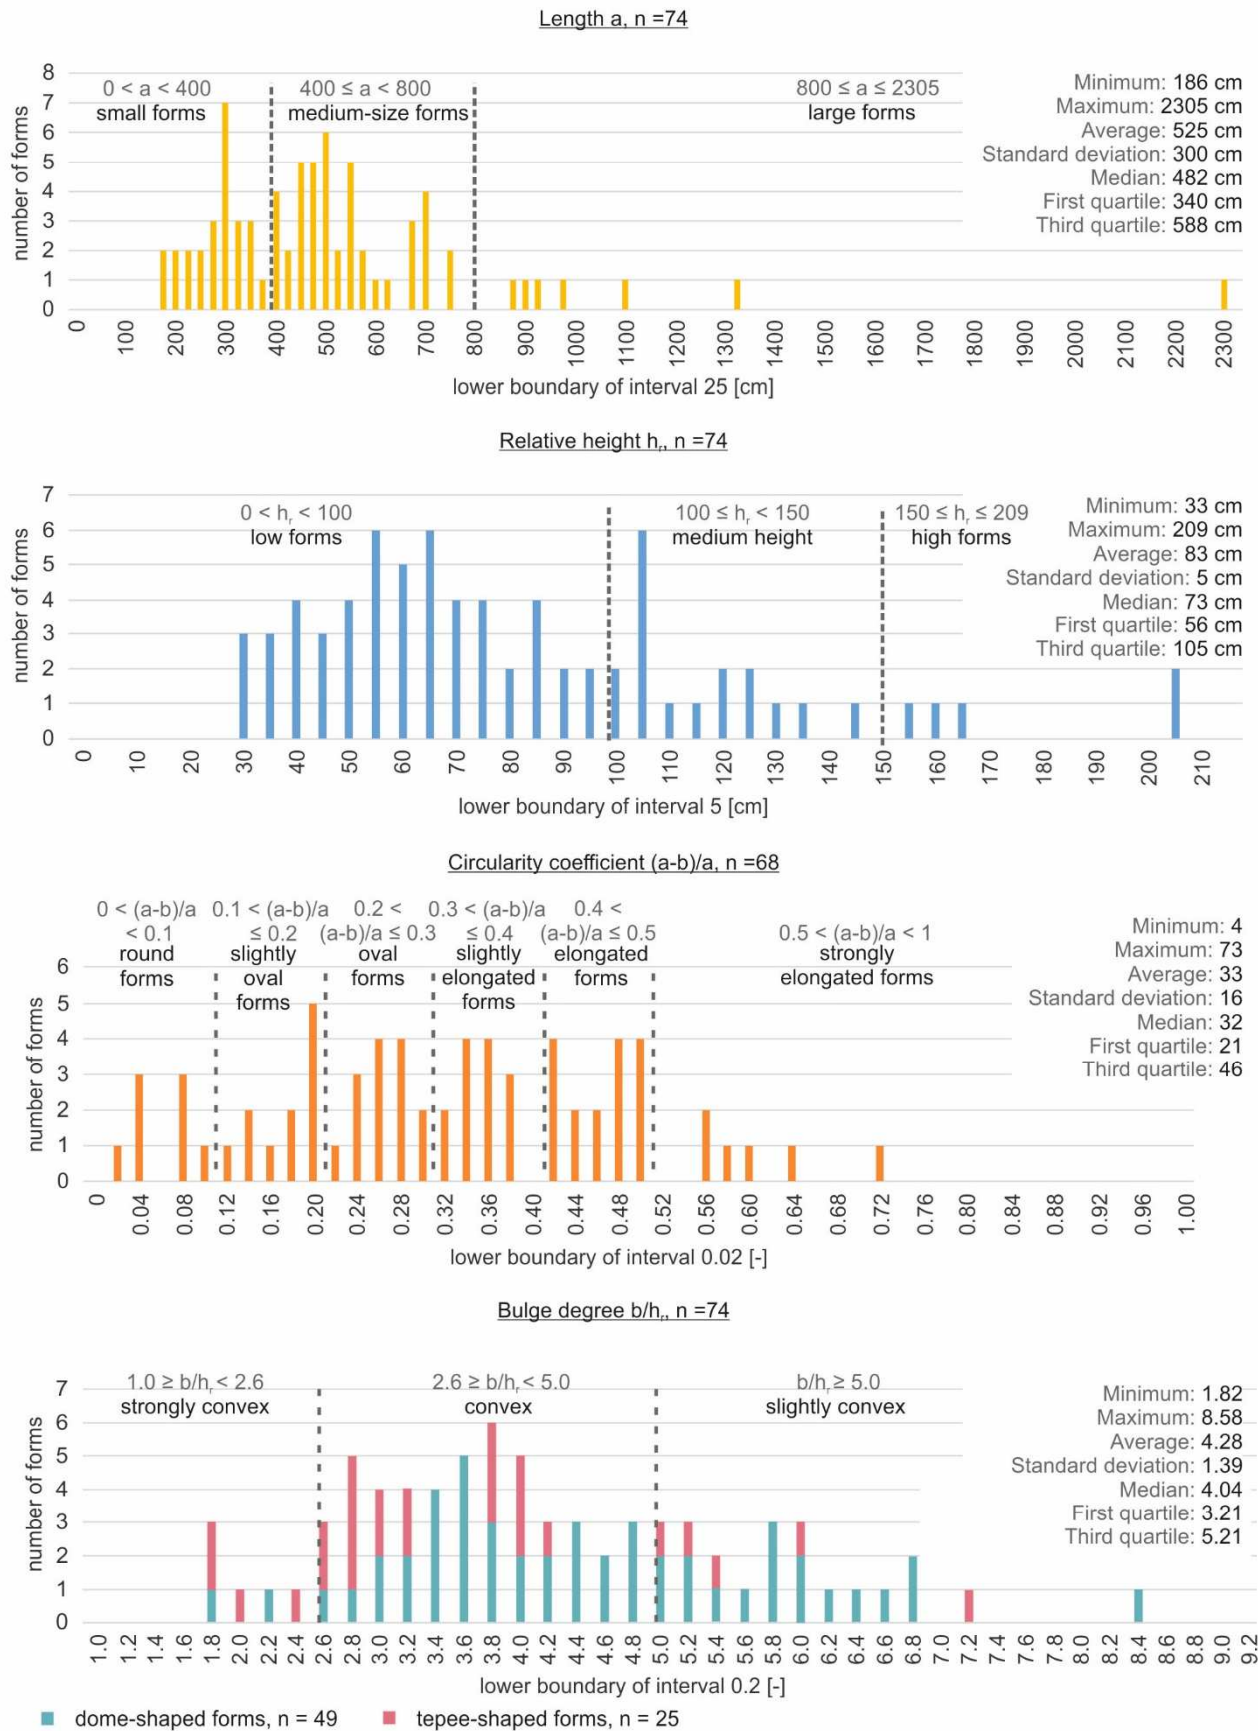

Figure S6

Dependence of relative height of hydration landforms on length, width, bulge degree and coefficient of circularity, taking into account classification of forms according to relative height.

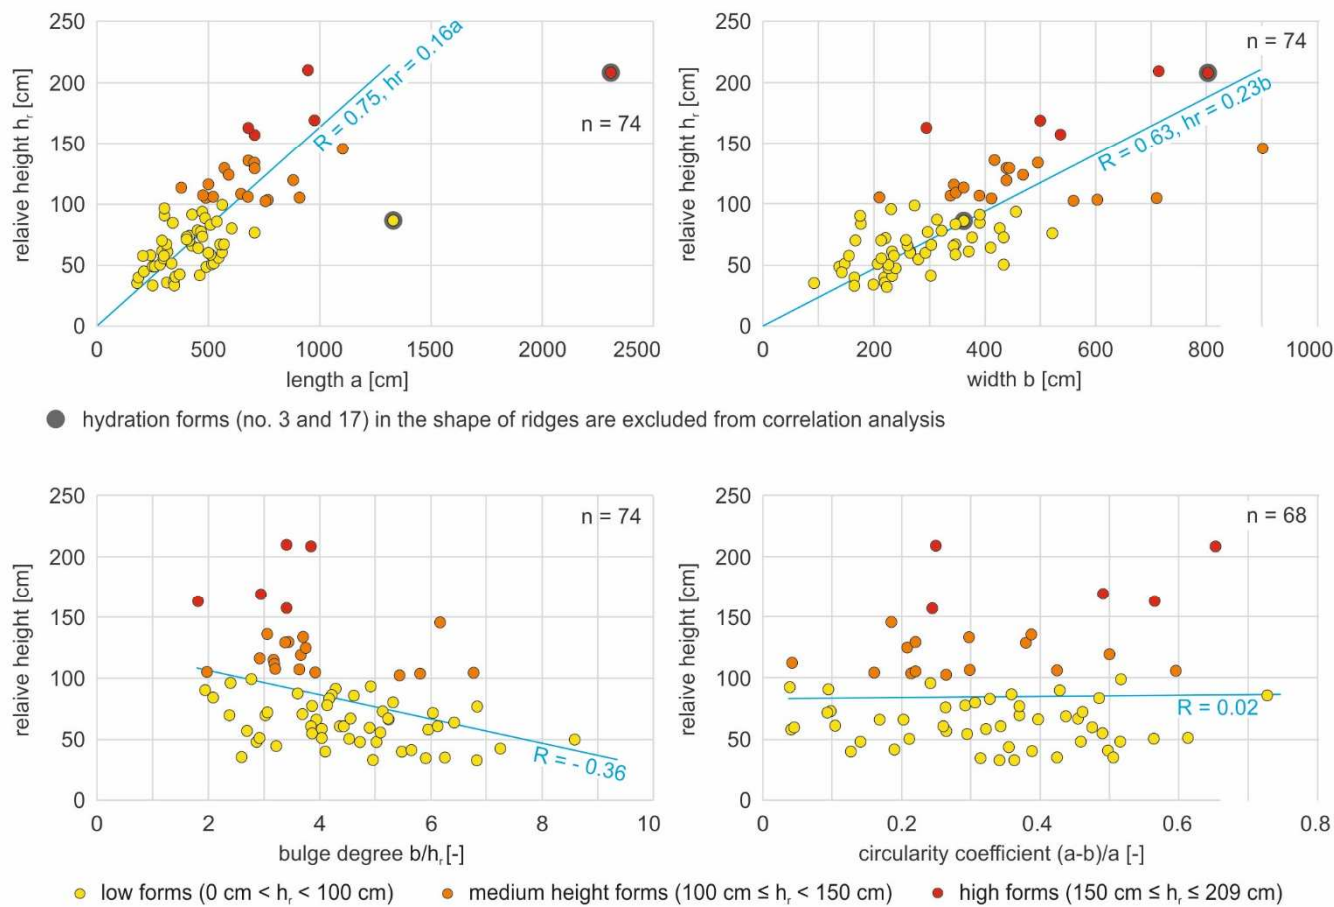

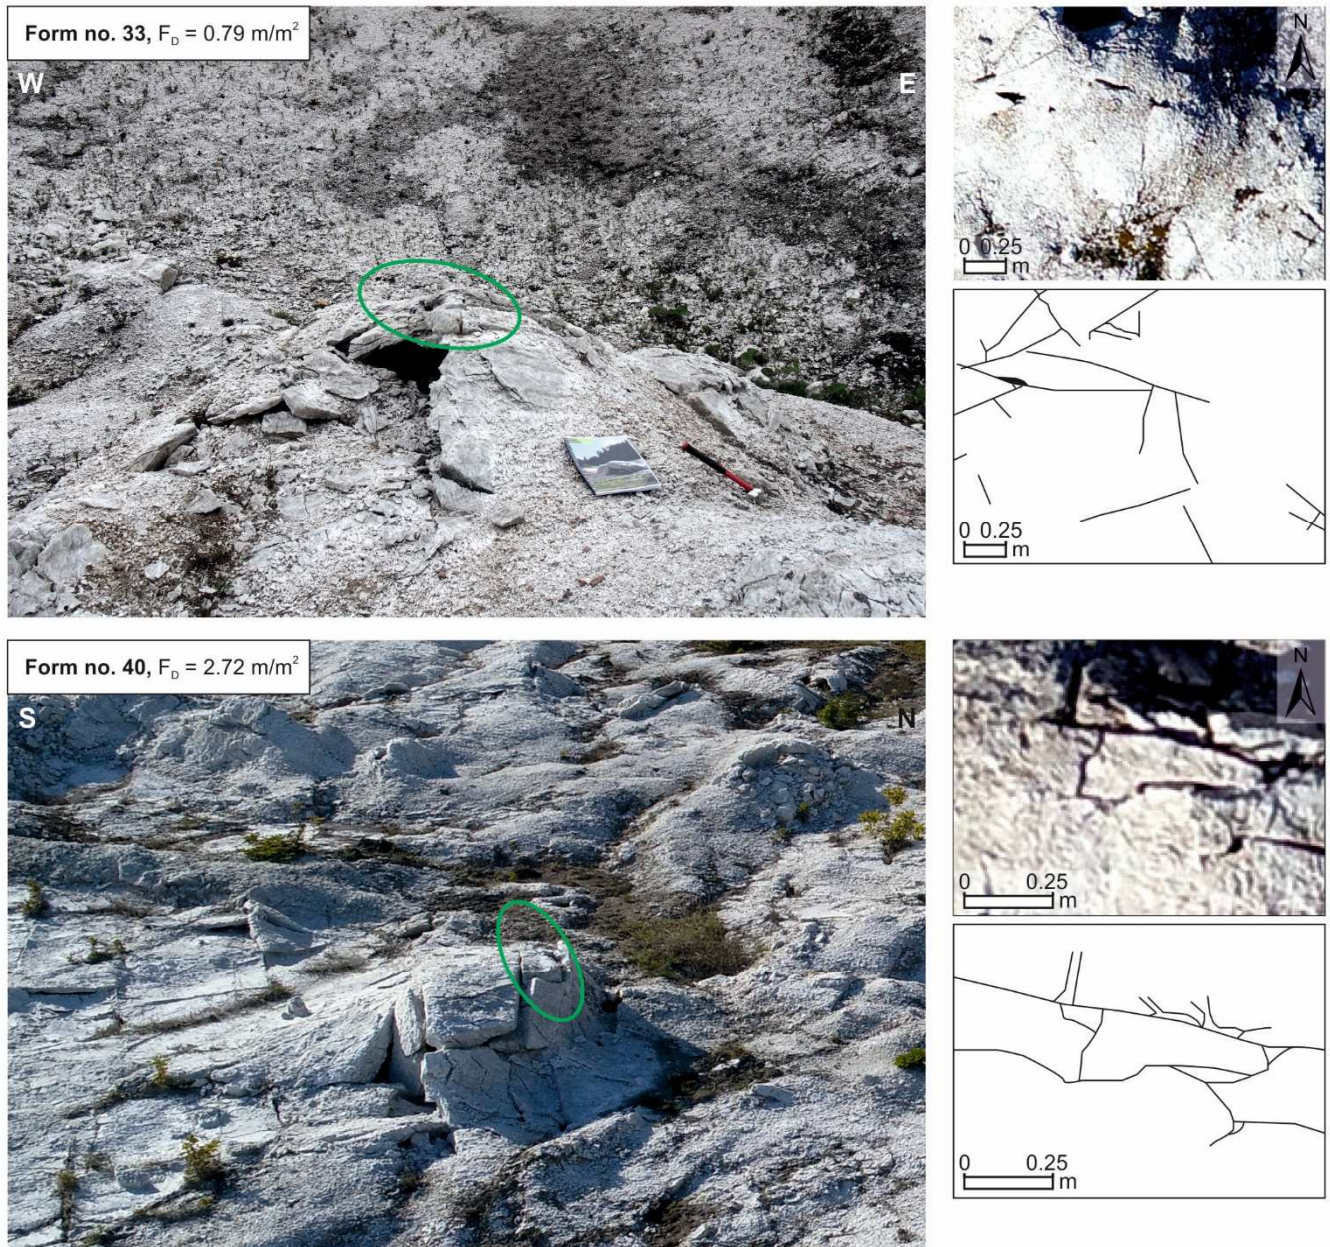

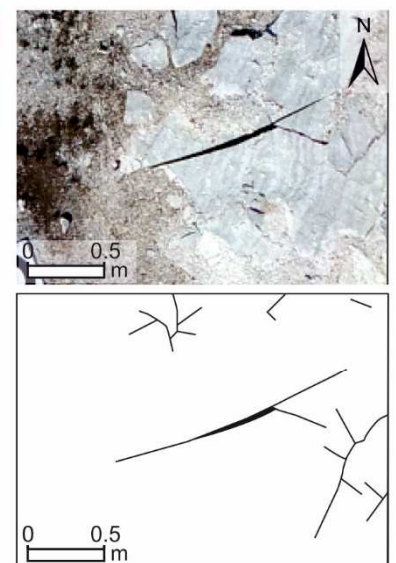

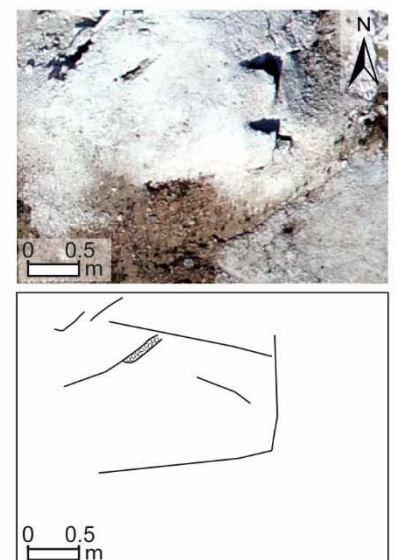

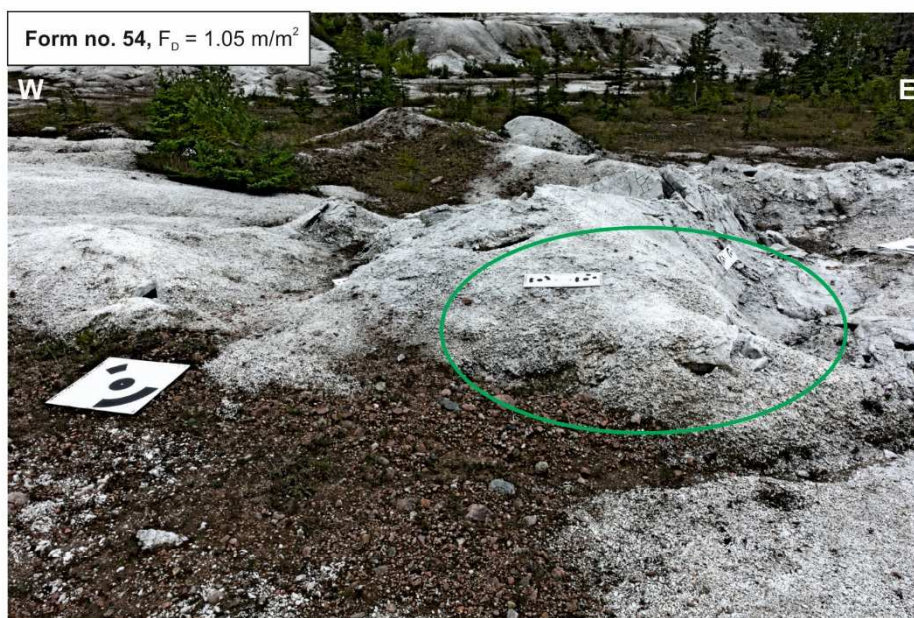

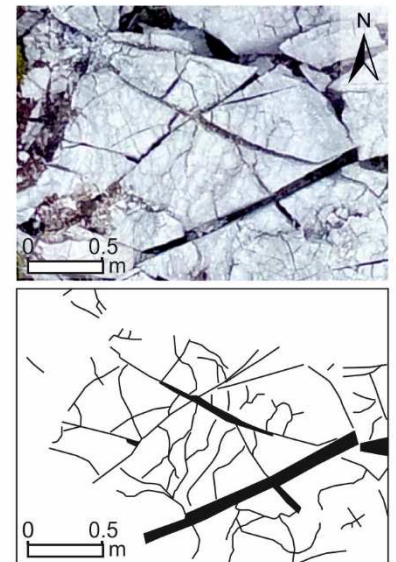

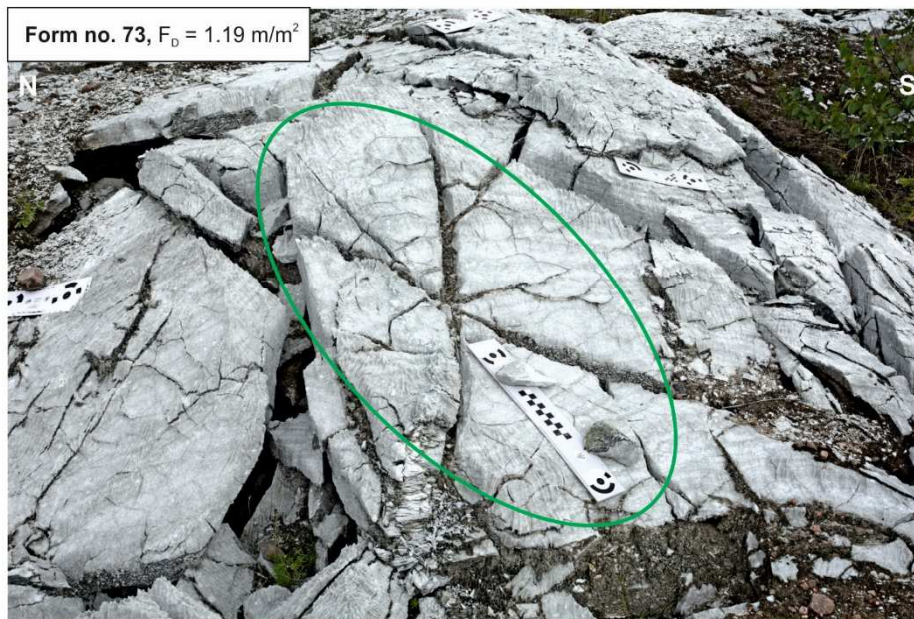

Figure S7

Pattern of fractures within hydration forms, with identifying no. and surface density of fractures given at the upper left (see Figure S3 for location of the forms); green circle marks place of the orthophotomap presented on the right.

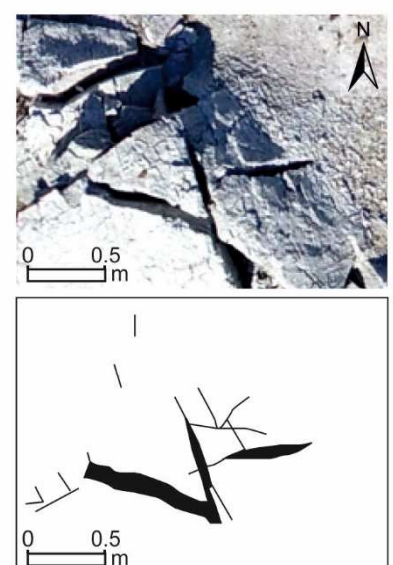

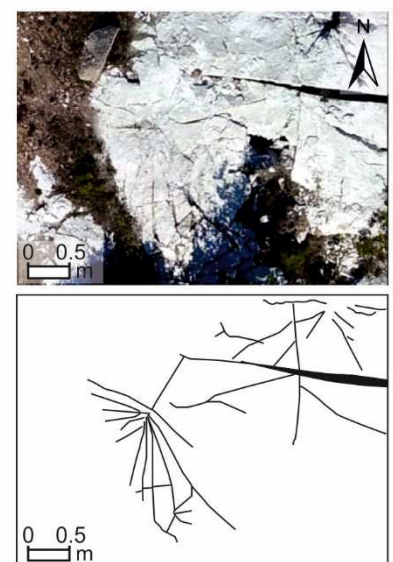

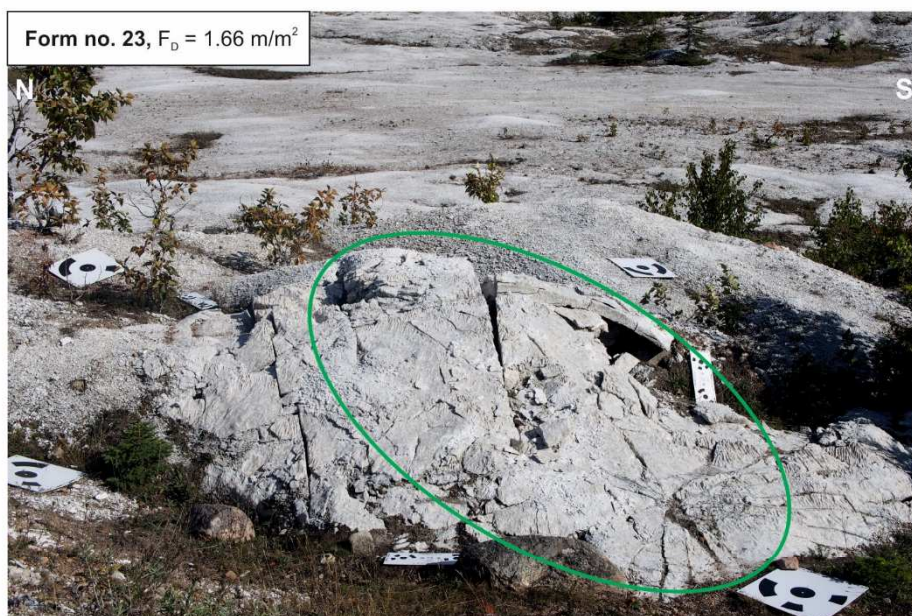

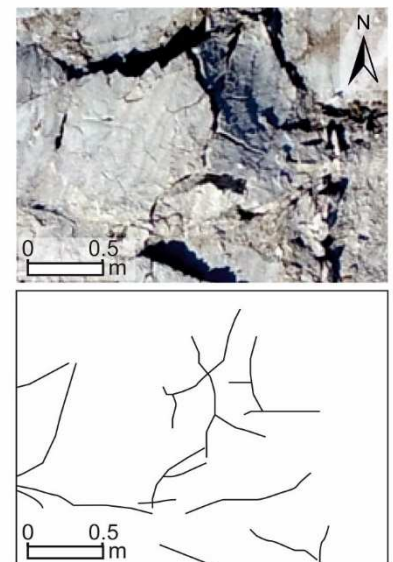

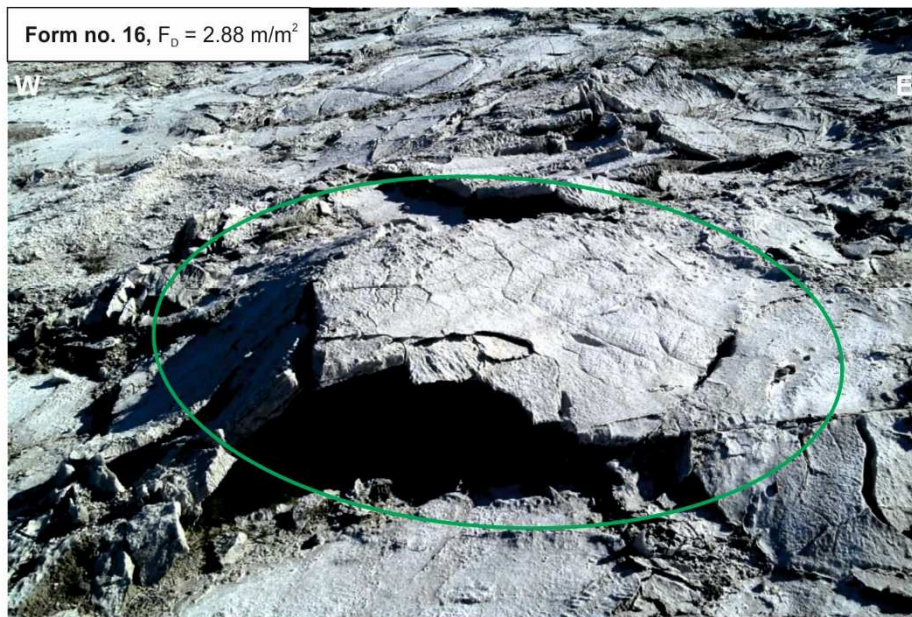

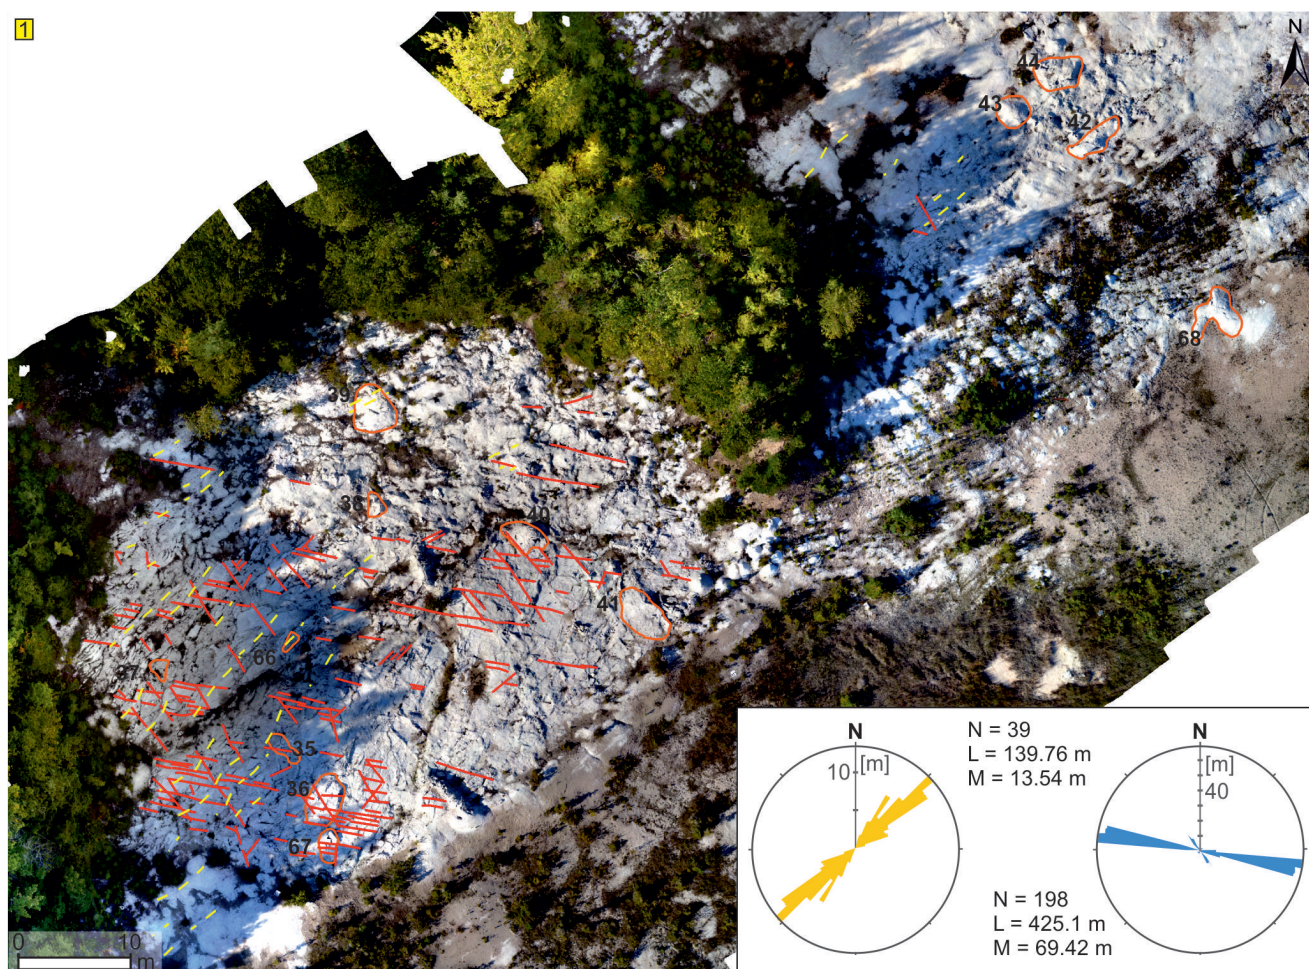

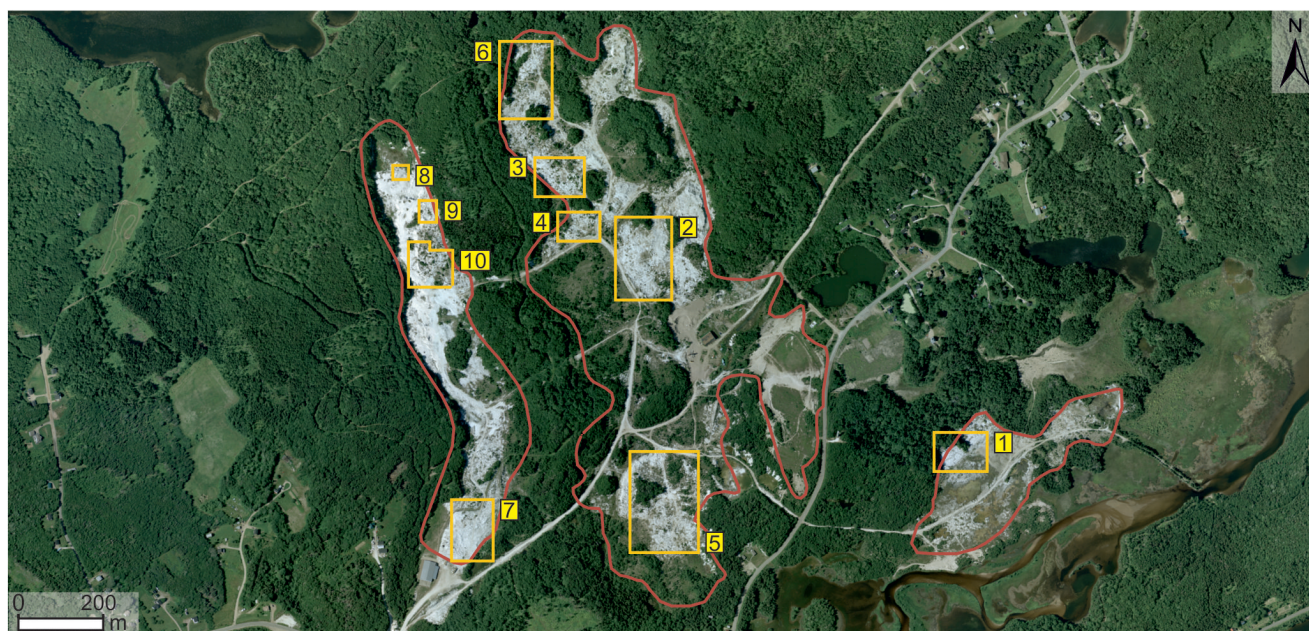

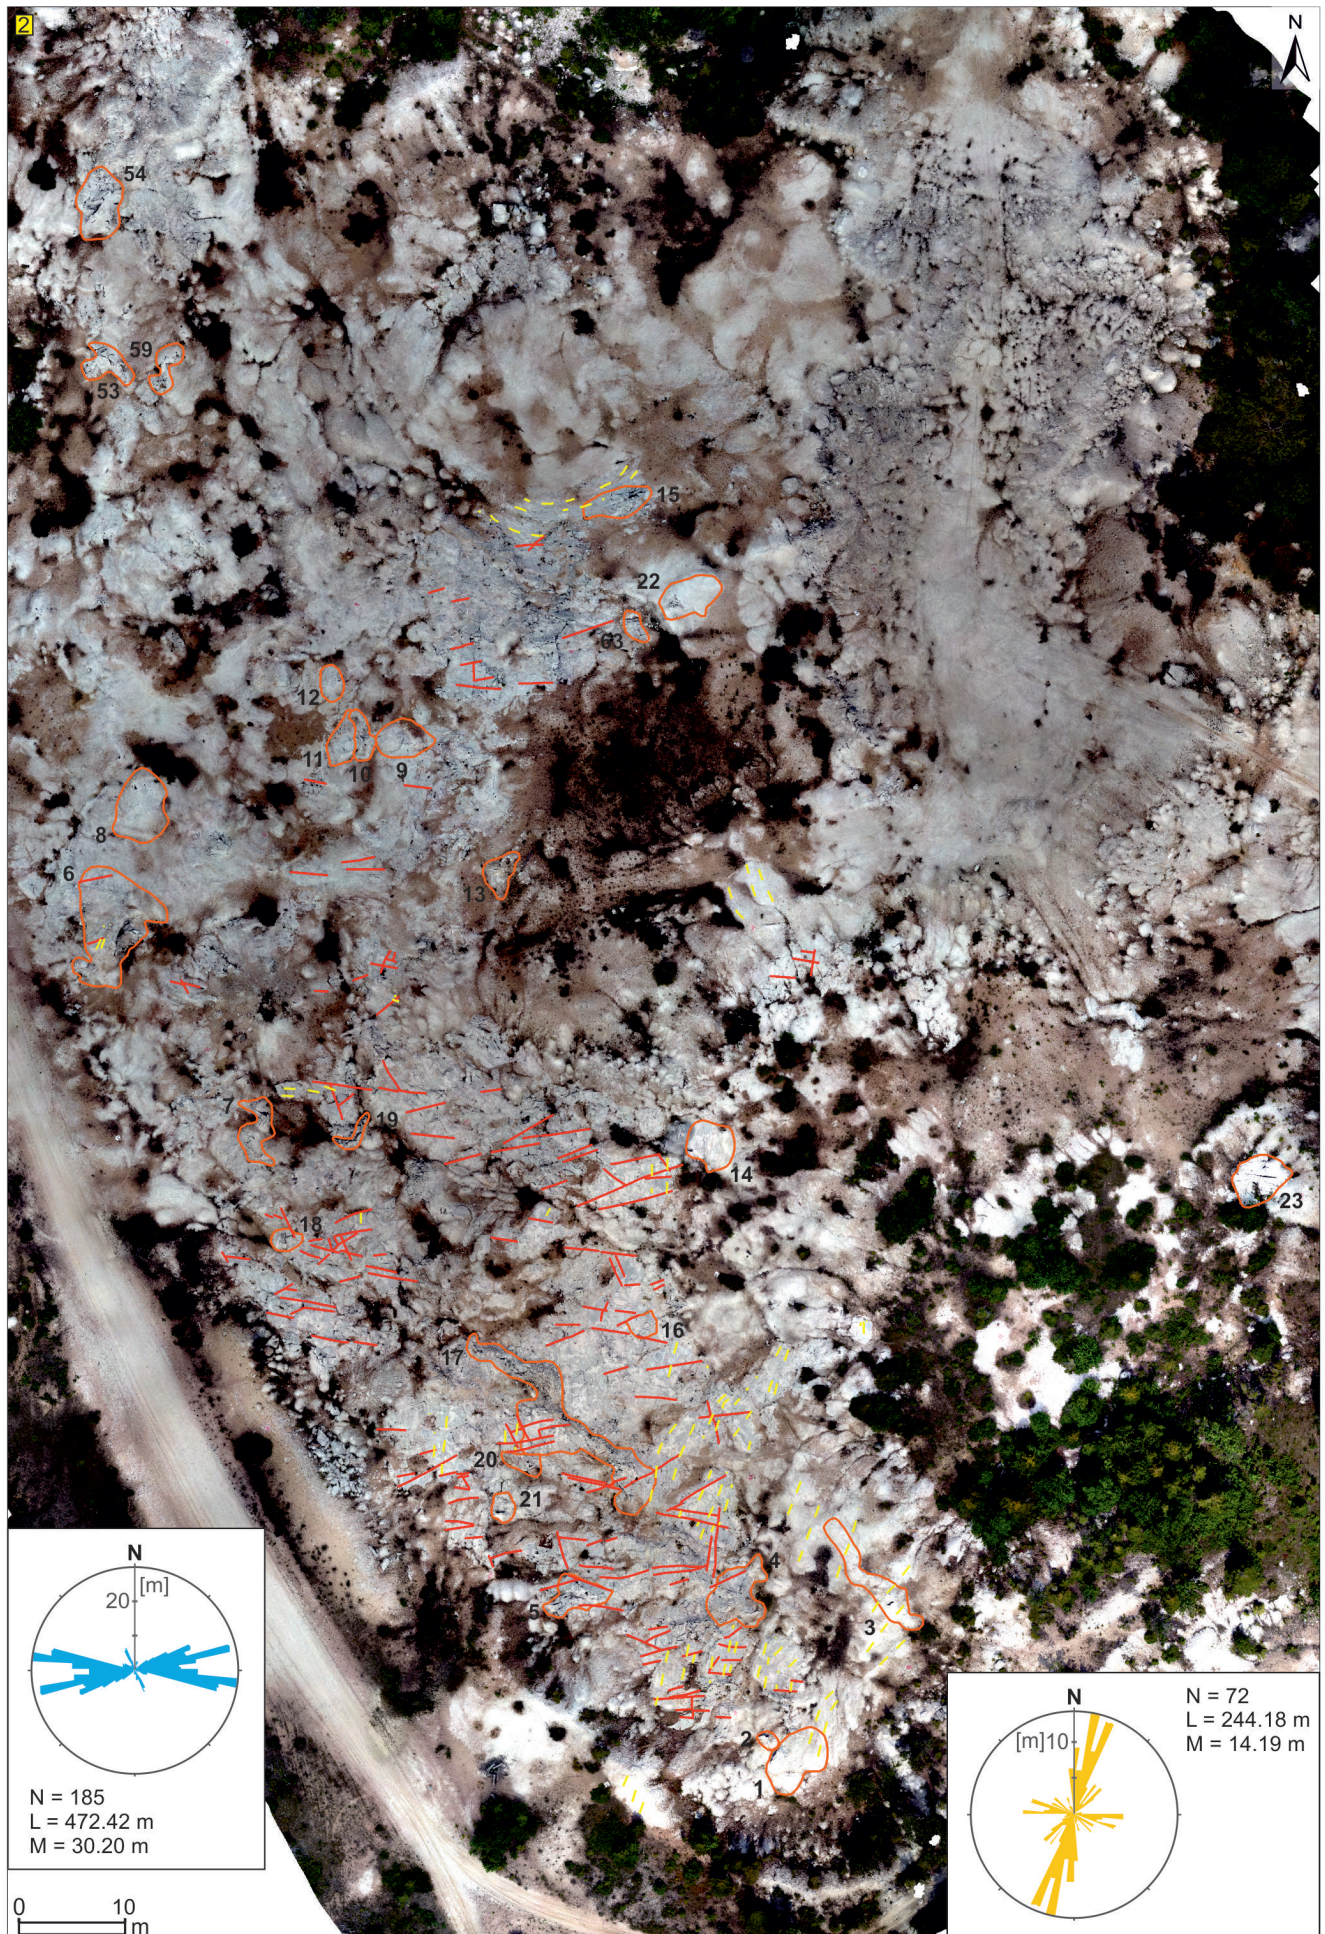

Figure S8

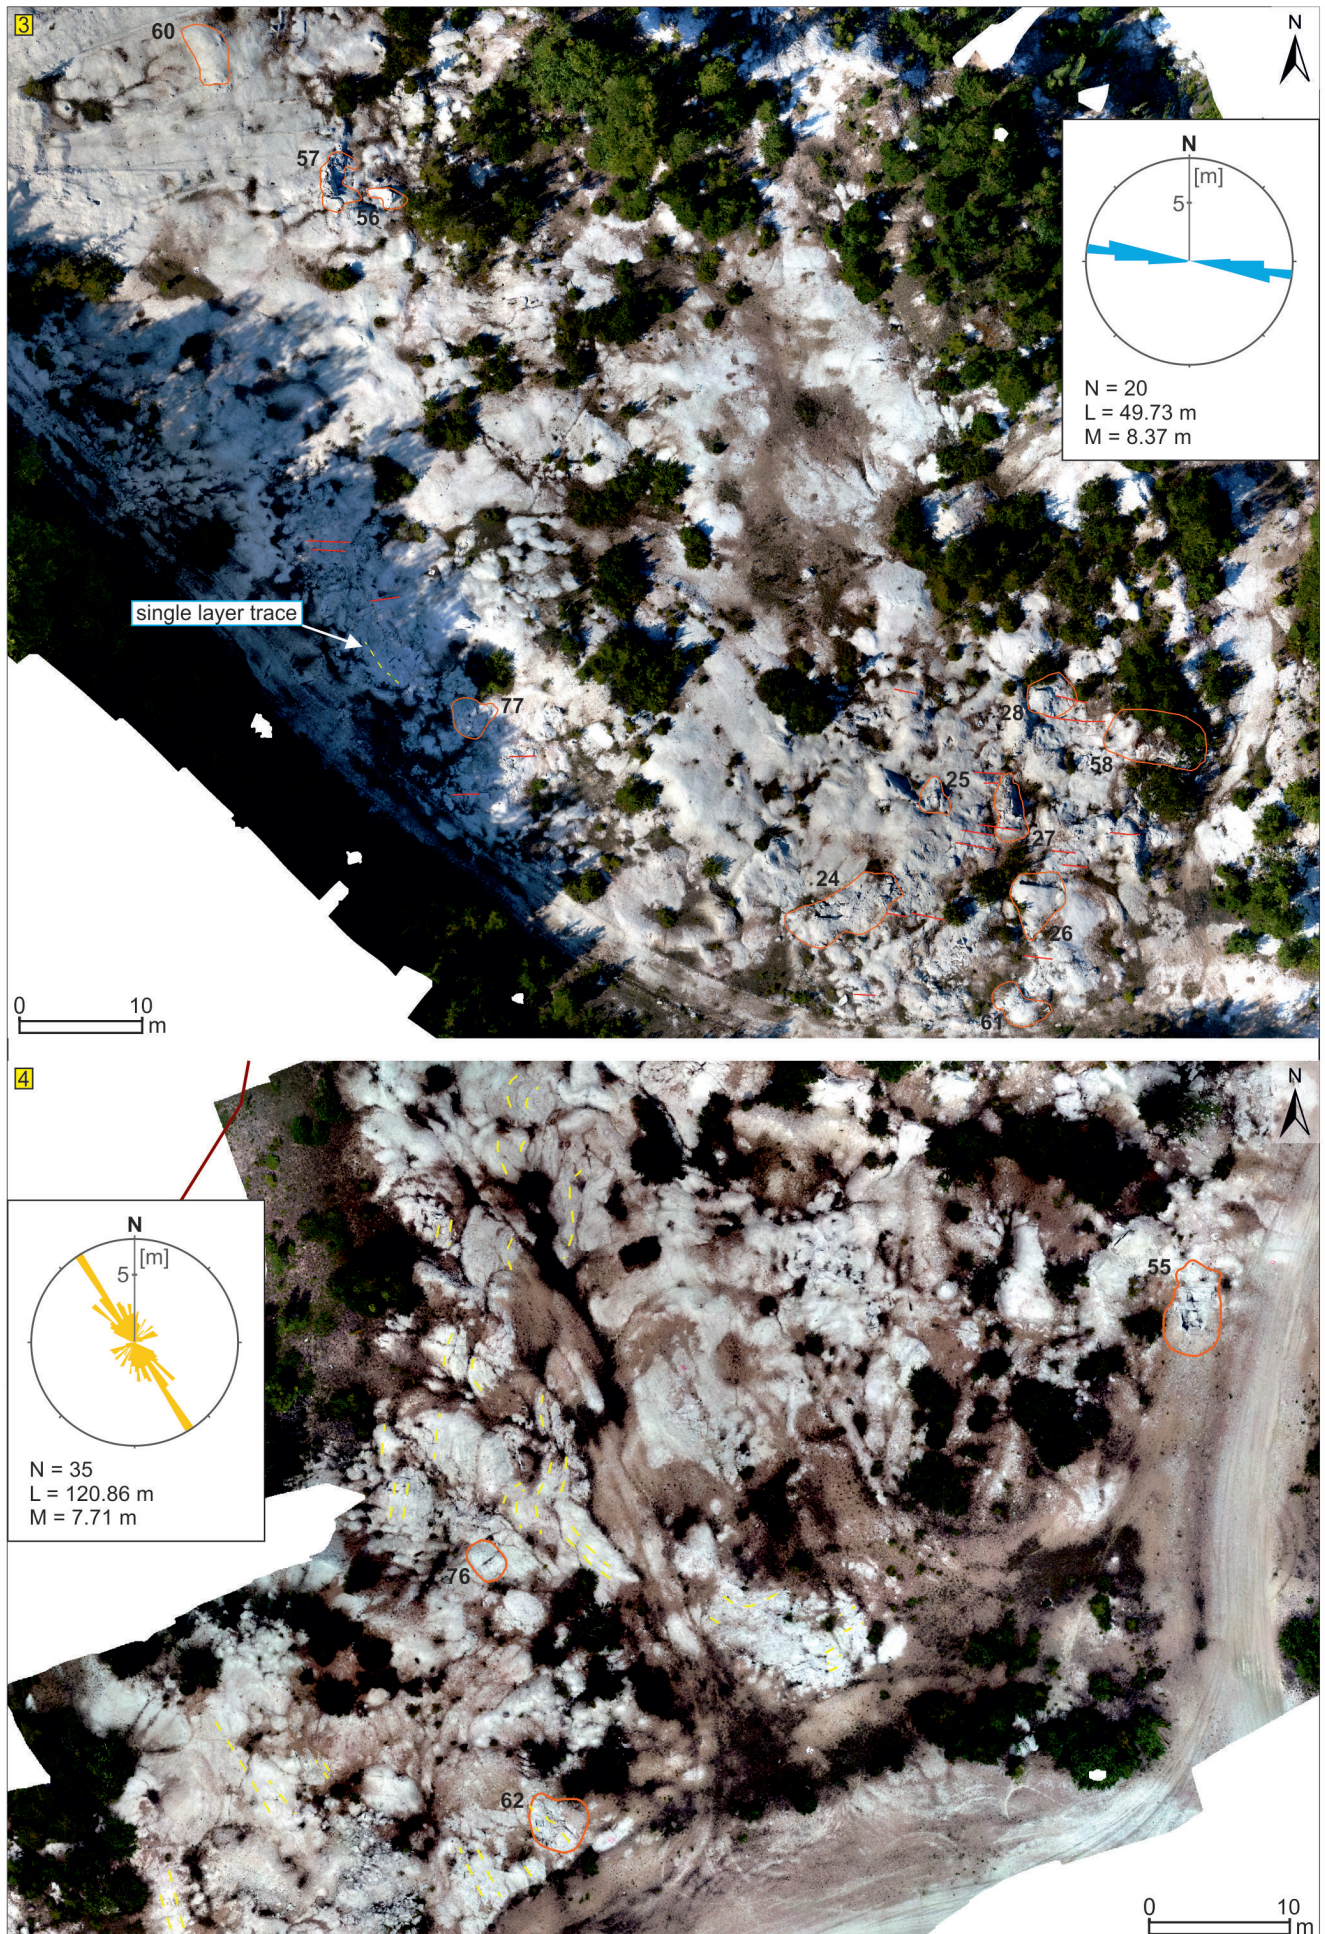

Traces of fractures and rock layers on the orthophotomaps of the quarry bottom and their rose diagrams (N – total number of fractures, L – total length of fractures, M – maximum length of a circle radius).

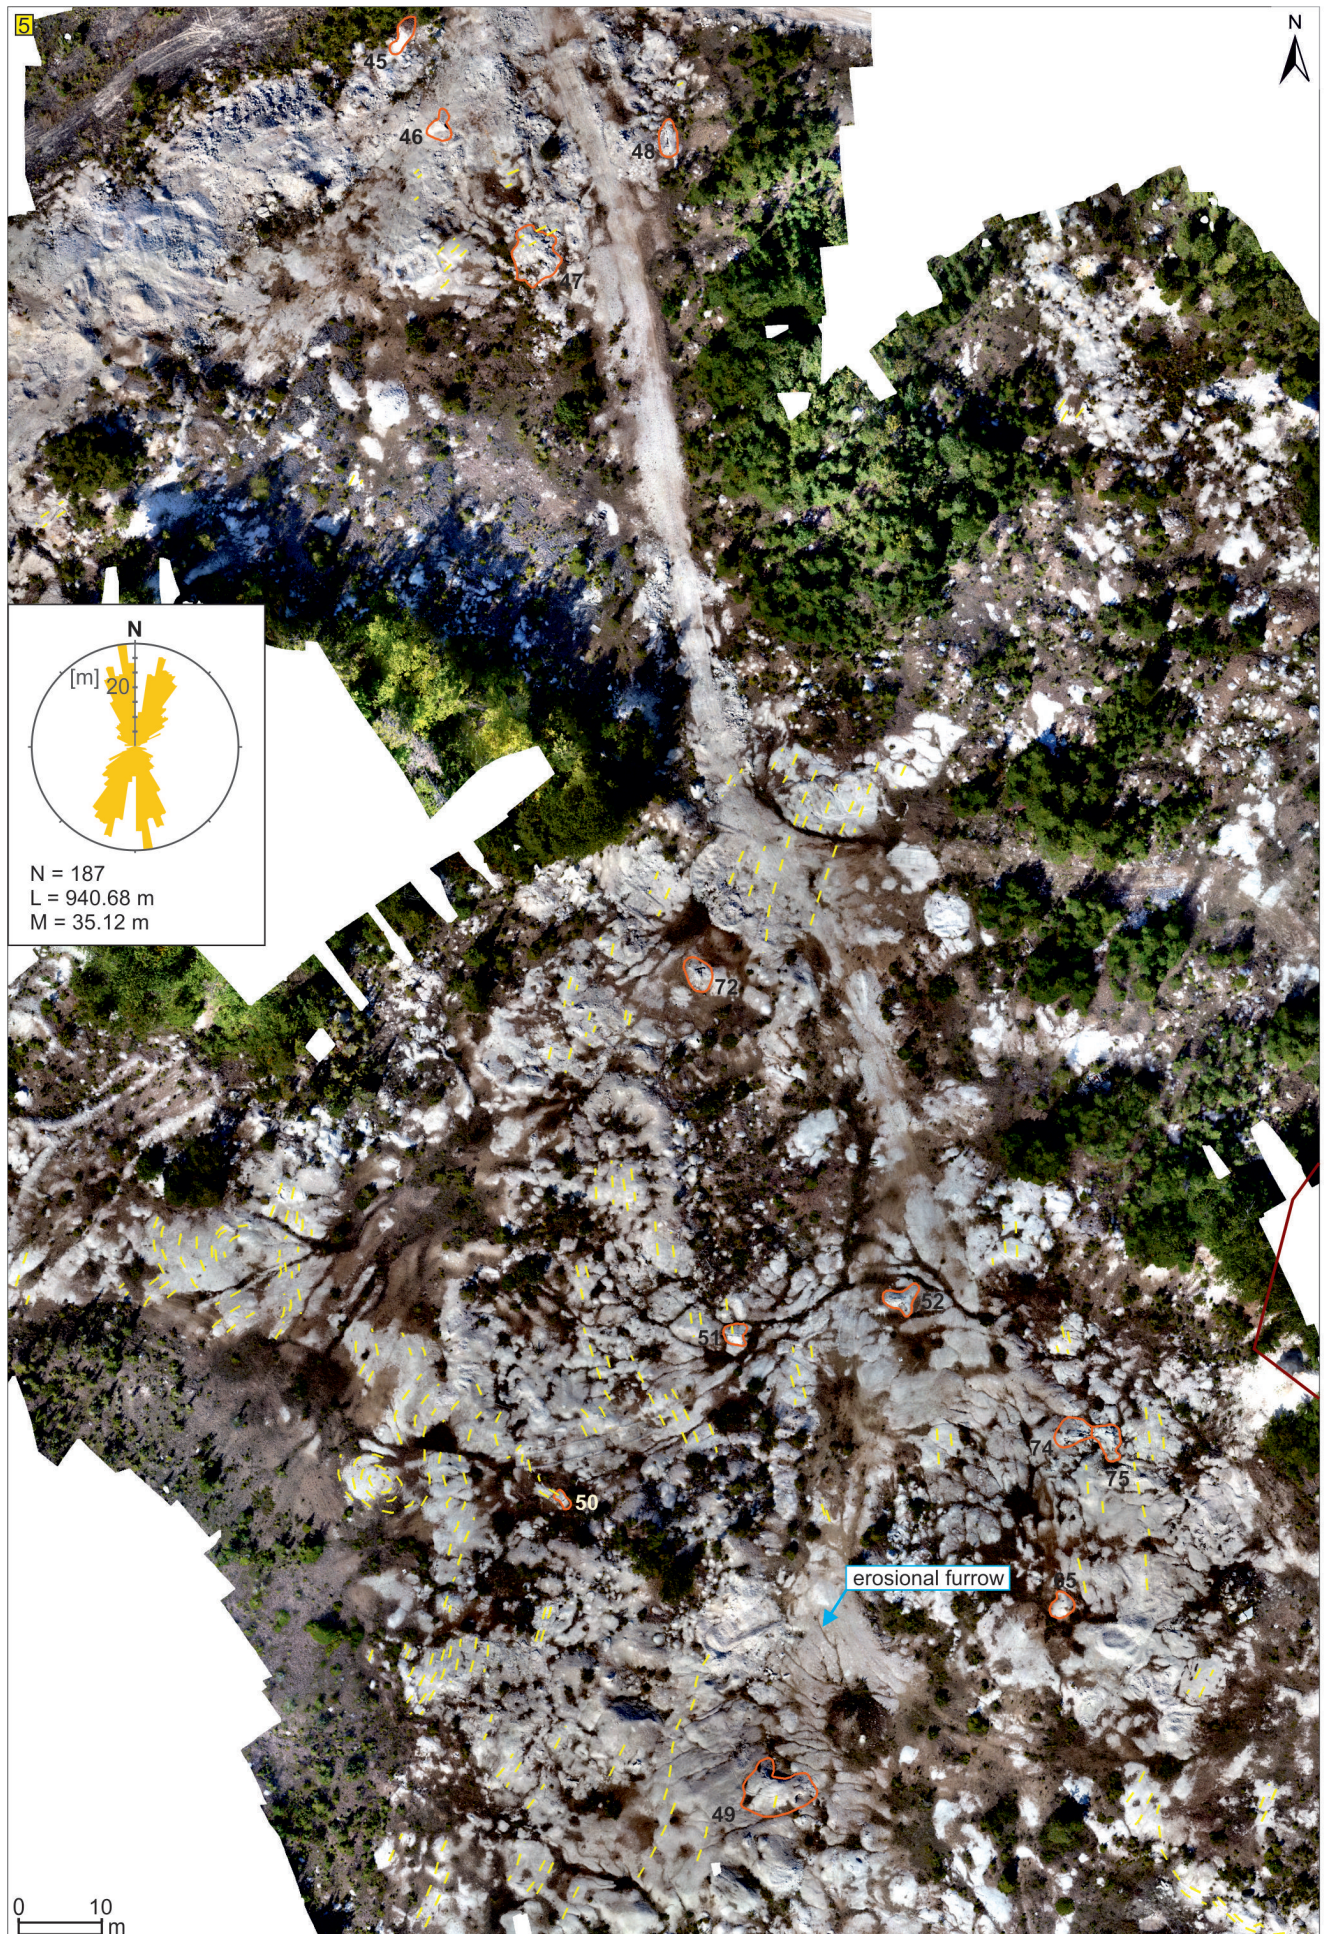

Legend

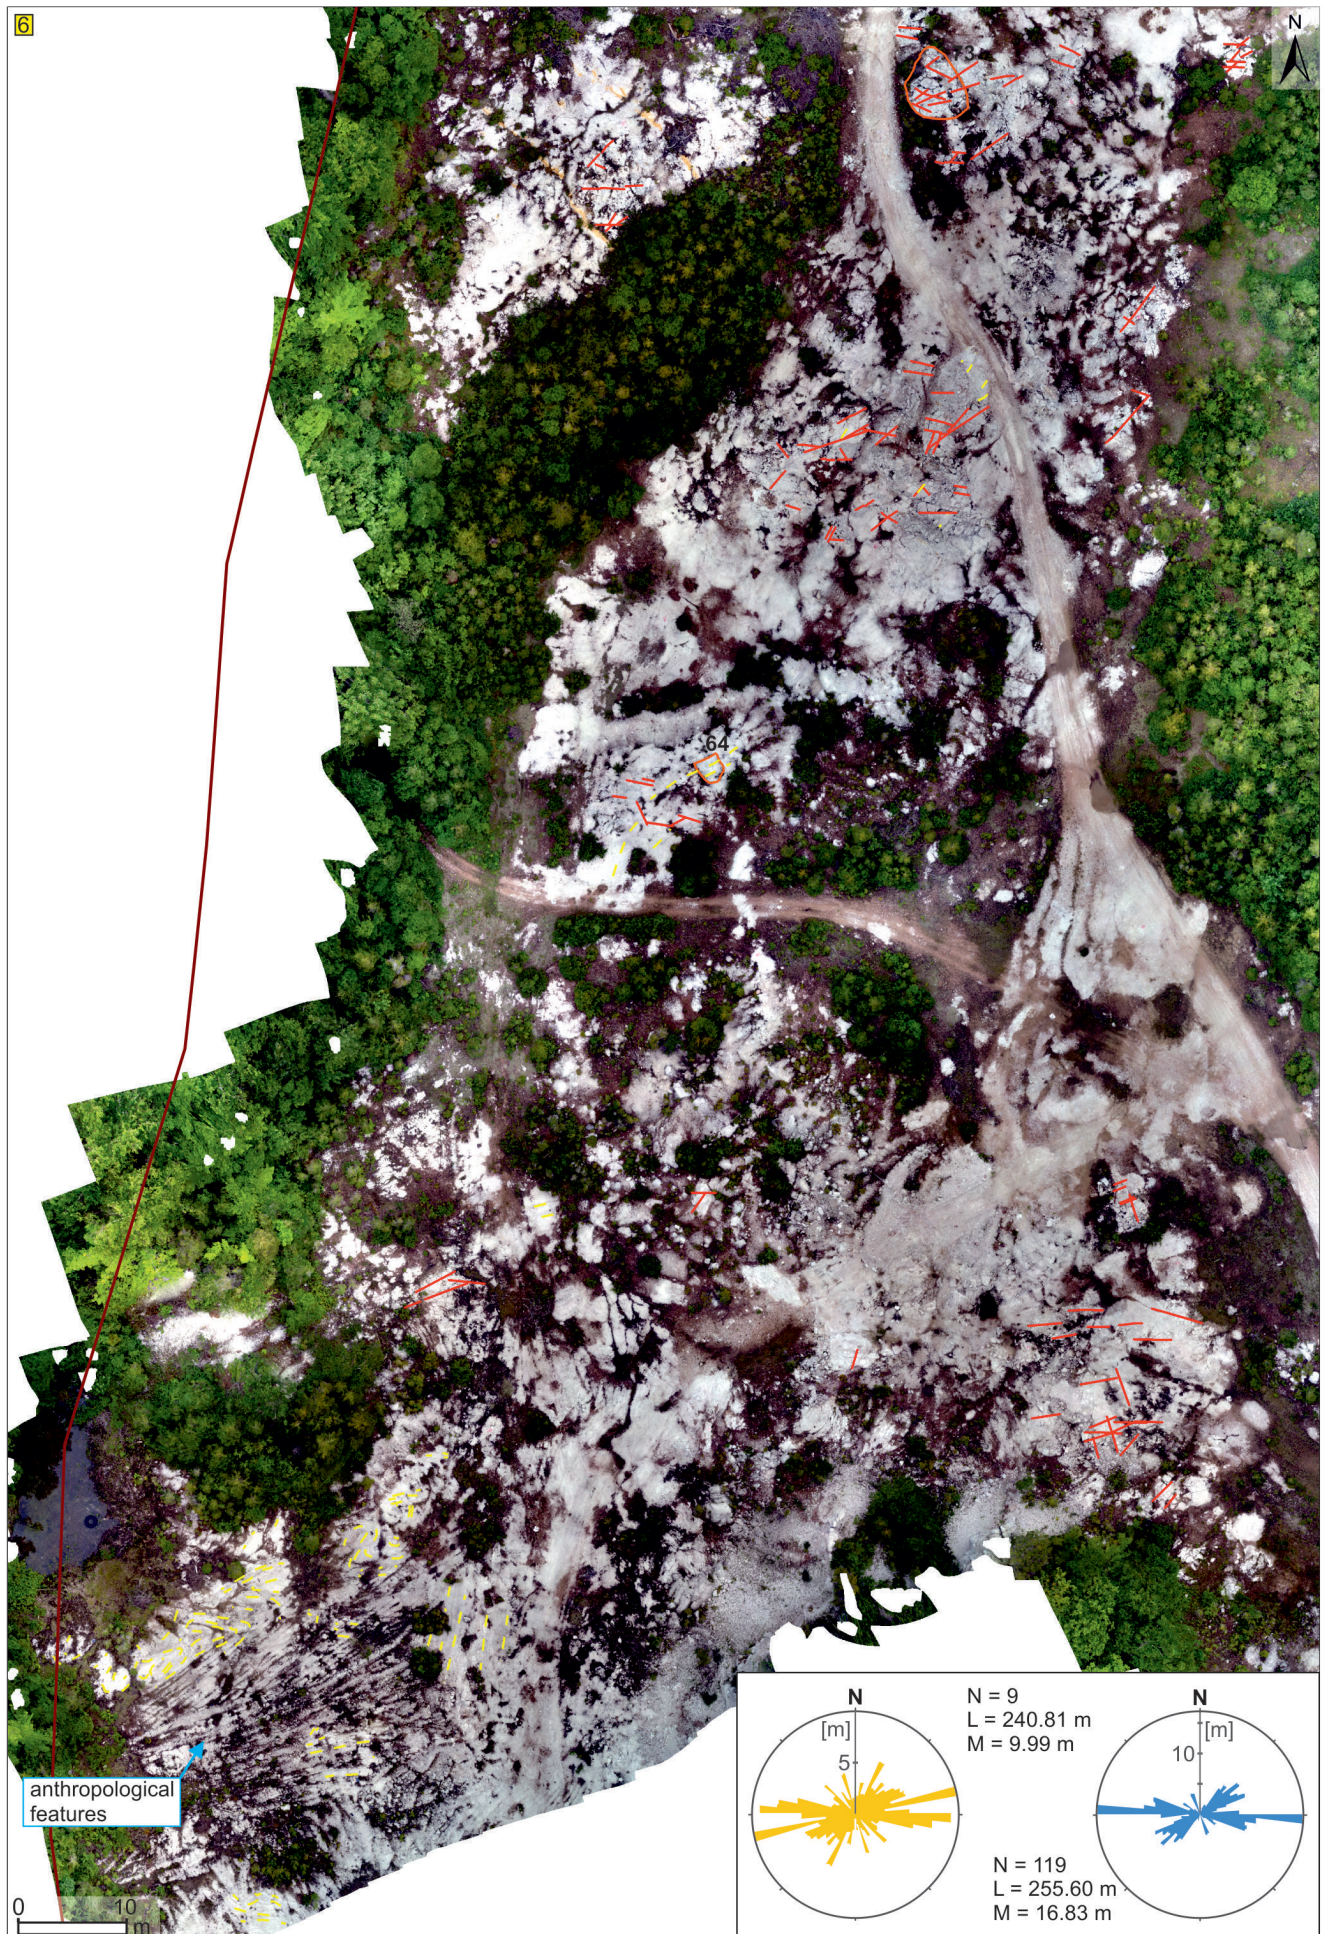

- extent of the quarry
- traces of gypsum-anhydrite layers
- traces of fractures, mostly joint sets
- extent of the hydration form and its identifying number
- rose diagram of layering
- rose diagram of fractures

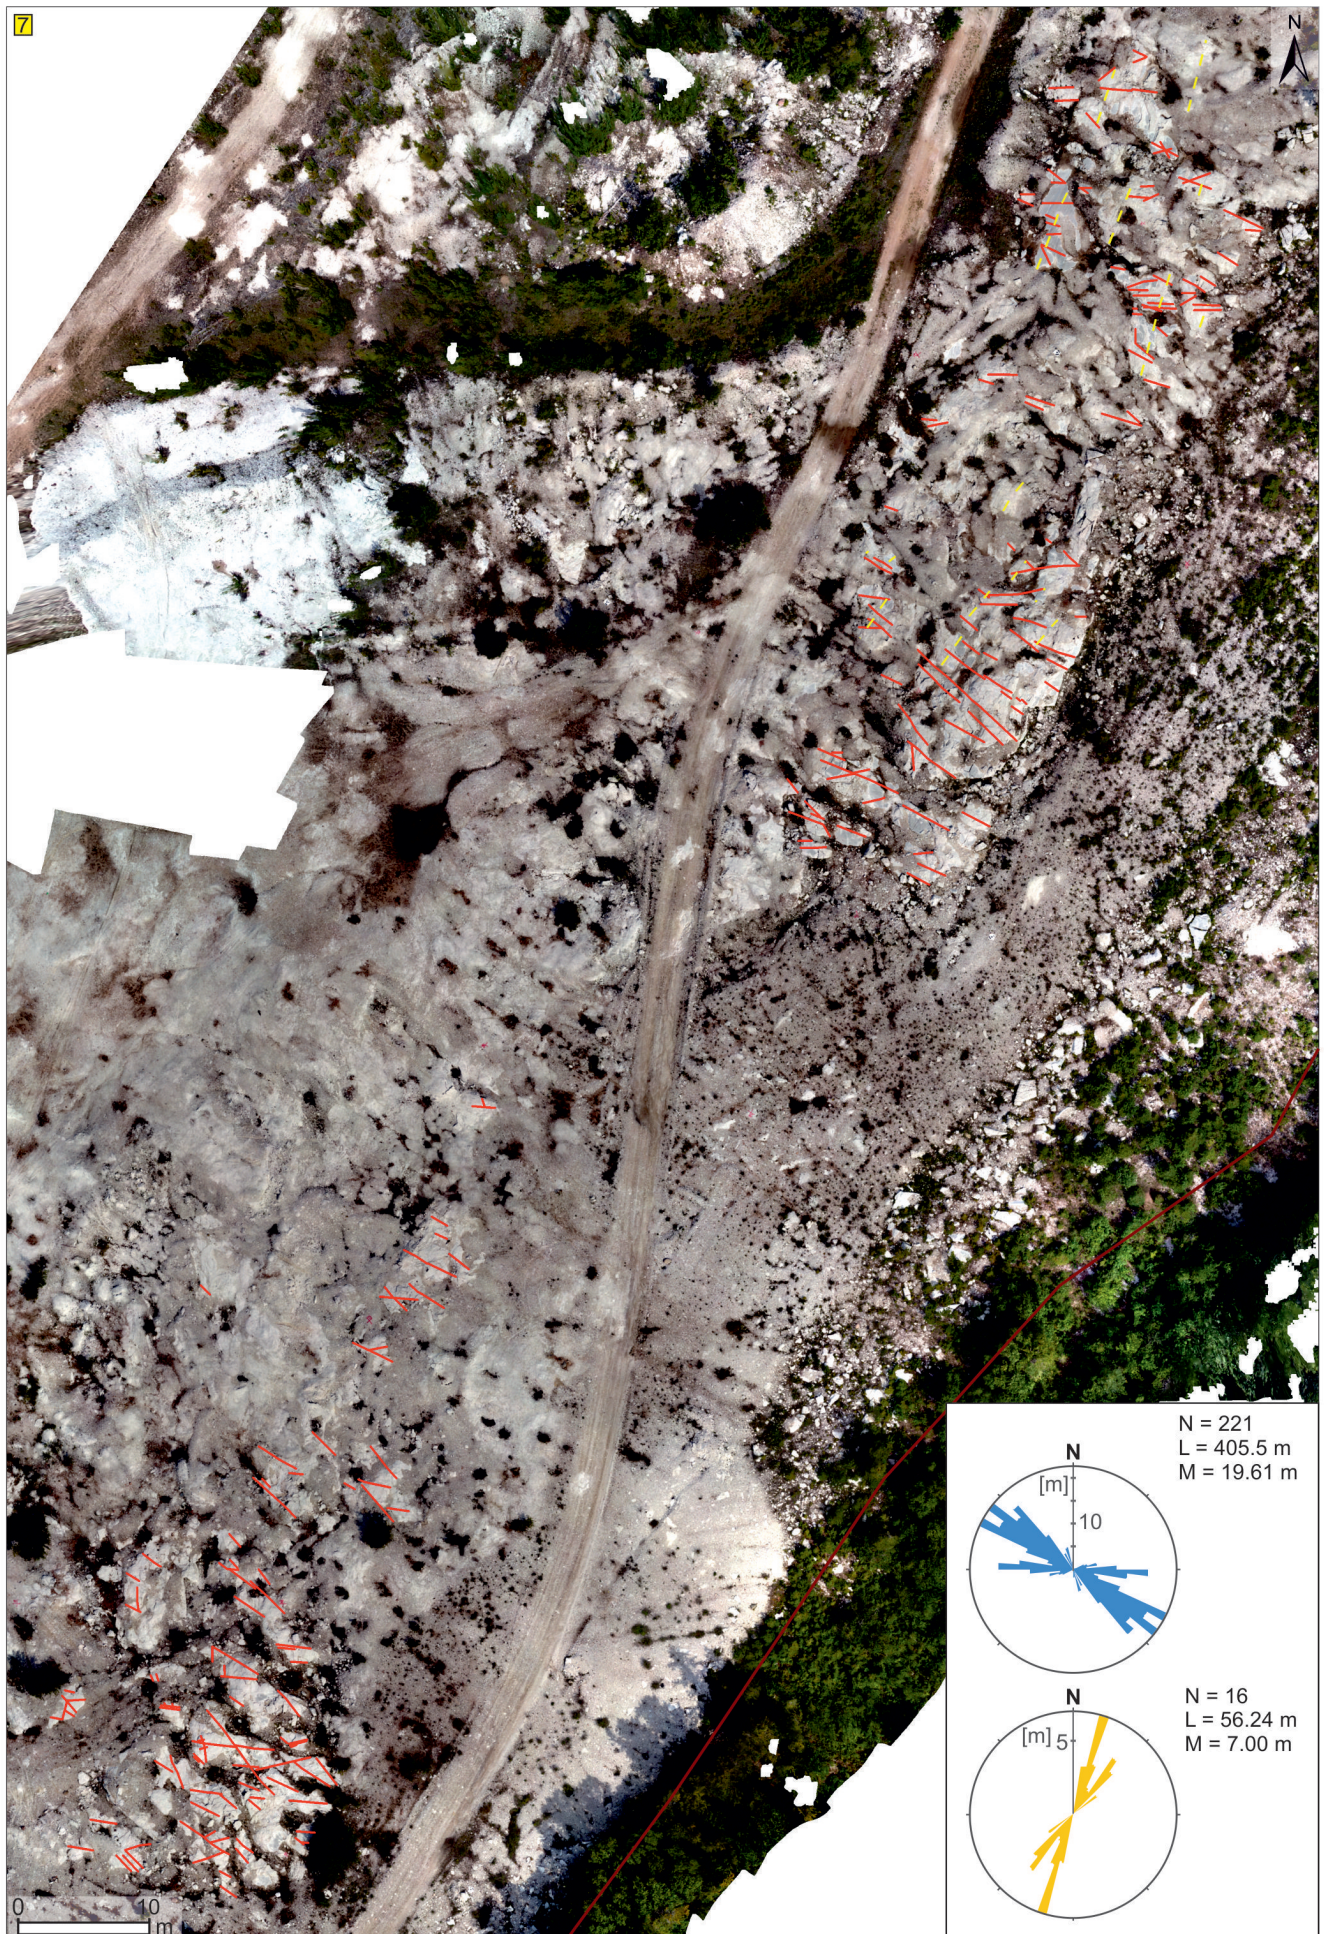

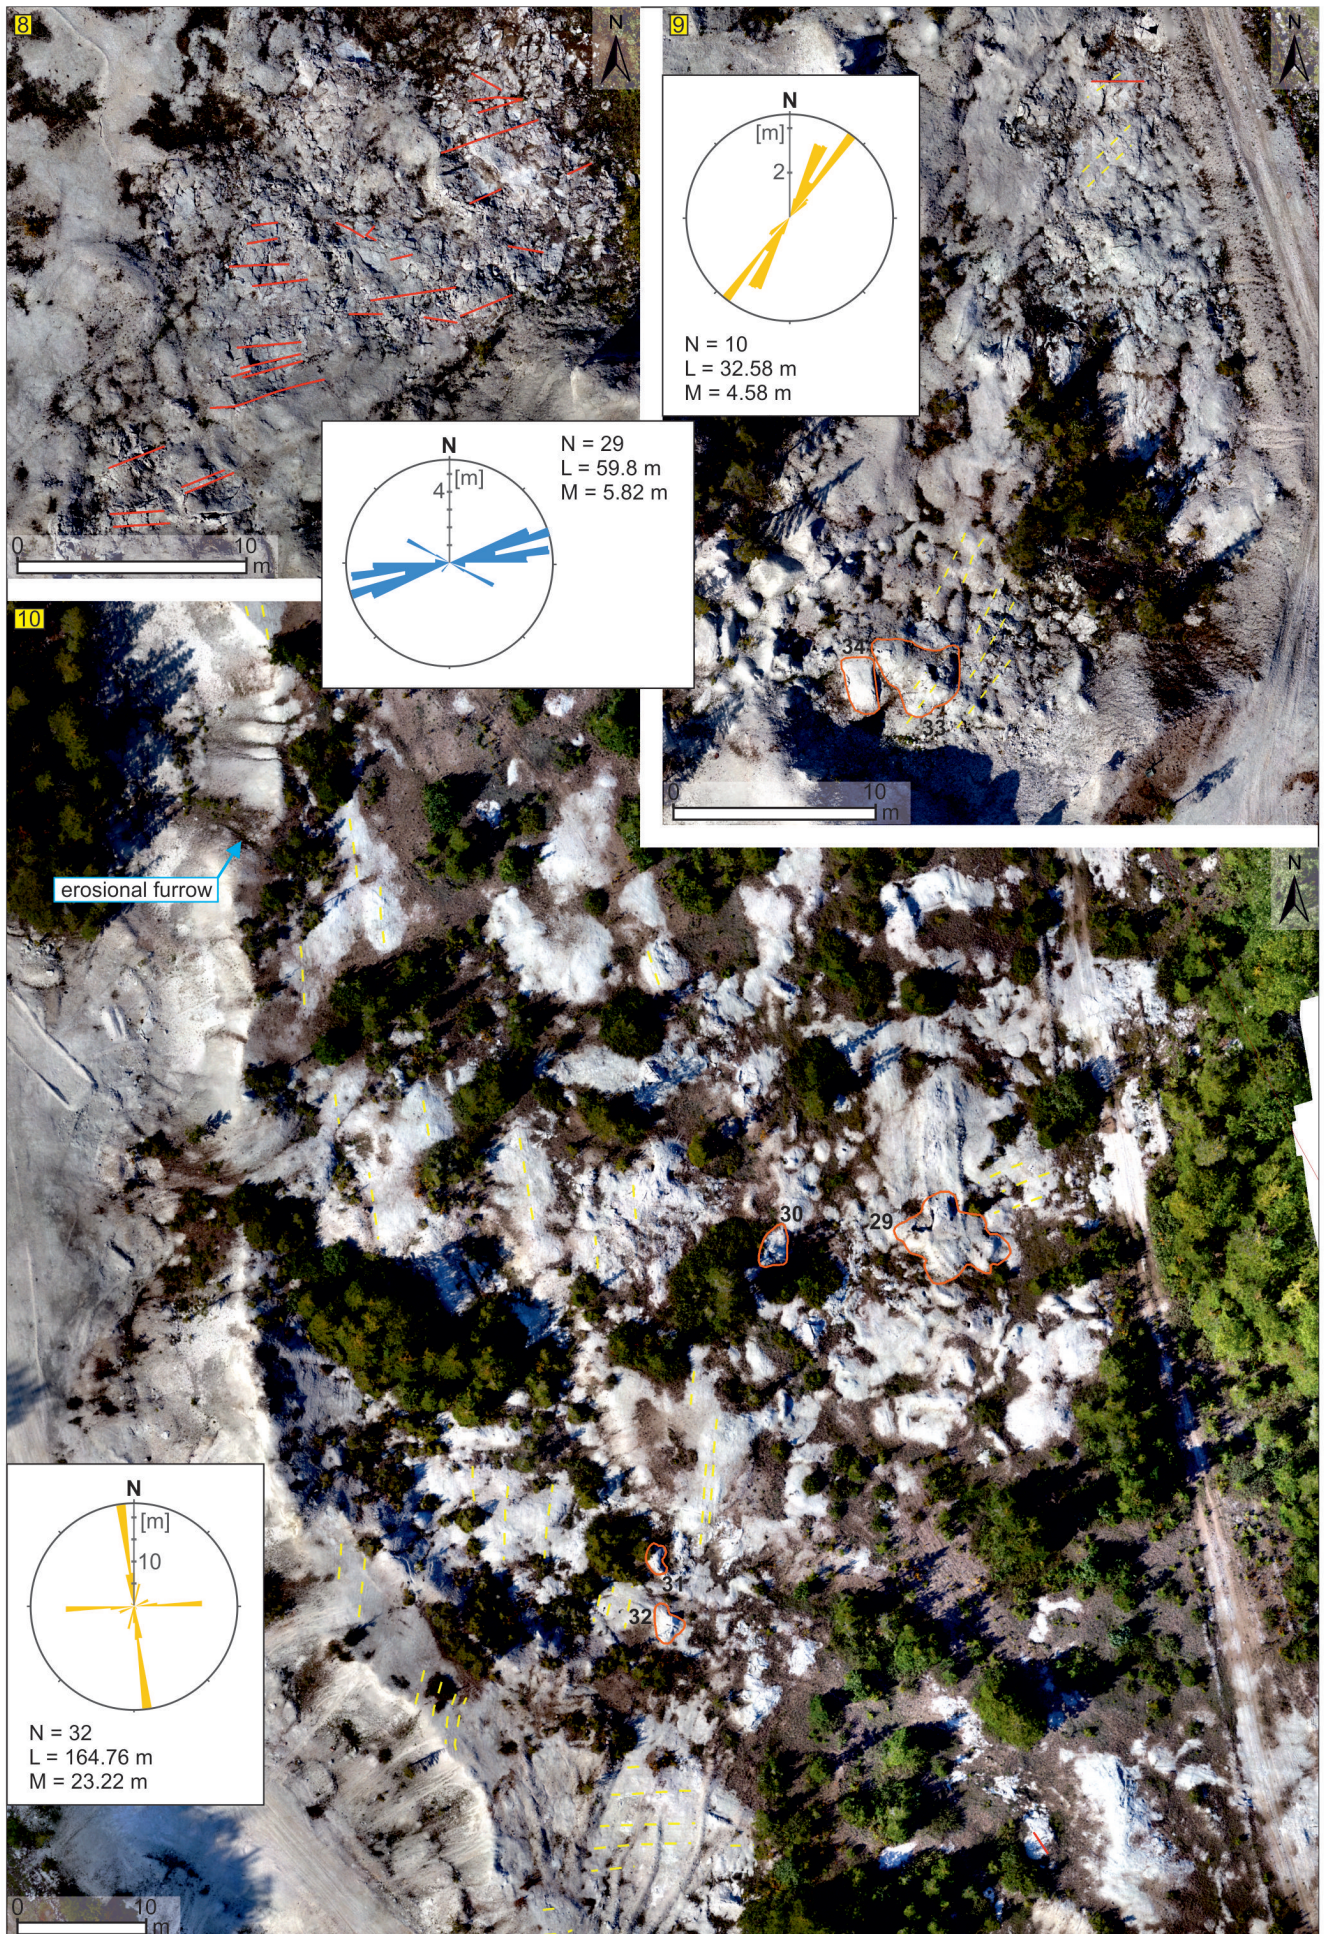

Figure S9
Exemplary hydration landforms influenced by structural types of bedrock.

Legend

- 1

extent of the hydration form and its identifying number
- traces of gypsum-anhydrite layers
- entrance to inner cavity of hydration form
