## Supplementary Figure and Legend

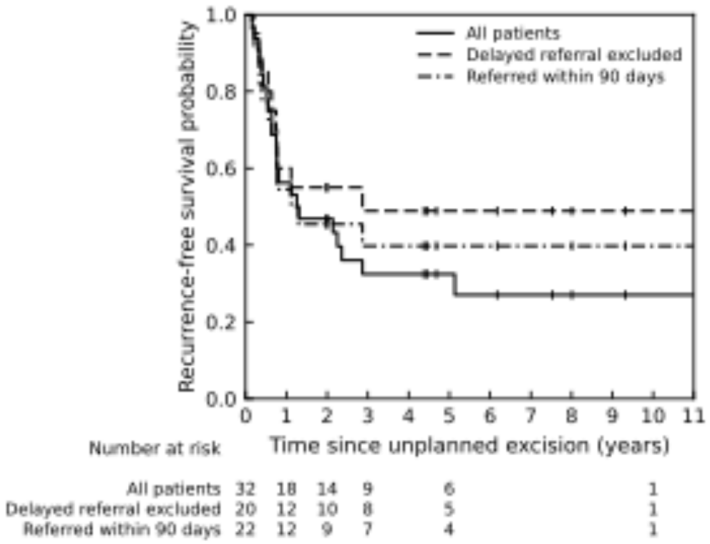

Figure S1. Sensitivity analyses of recurrence-free survival after unplanned excision. The solid line shows all 32 patients; the dashed line shows the 20 patients remaining after exclusion of the 12 patients who had been referred only after local recurrence had already developed; and the dash-dotted line shows the 22 patients who were referred within 90 days of the unplanned excision. Tick marks indicate censored patients, and numbers at risk are shown below the curve. The x-axis is truncated at 11 years, as in Figures 1 and 2. RFS, recurrence-free survival.

**Note on the survival estimates shown in this figure:**

- All patients (n = 32): 1-year RFS 56.2%; 5-year RFS 32.5%; median RFS 15.1 months.
- Delayed referral excluded (n = 20): 1-year RFS 60.0%; 2-year 55.0%; 3-year 48.9%; median RFS 34.4 months.
- Referred within 90 days (n = 22): 1-year RFS 54.5%; 5-year RFS 39.8%; median RFS 13.4 months.
- In both sensitivity analyses, local recurrence developed in approximately half of the patients and remained concentrated in the first postoperative year.
