

# Cardiovascular prediction model test codes

- Dataset: National Health Insurance Service-Health Screening (NHIS-HealS) datasets from 2009 to 2013 provided by Korea National Health Insurance Corporation. 4,699 patients whose ages are over 45 in 2013 was selected as a CVD diagnosed group, where the same number of random patients in the same age and sex distribution was selected as a non-CVD group.
- Diagnosis of cardiovascular diseases (CVD): ICD-10 codes (I20-I25) were extracted to be ground truth database for CVD diagnosis.
- Sampling of Non-CVD dataset: retrieved from the NHIS-HealS dataset in a random sampling way, confirming to the same statistical distribution of CVD dataset by considering the same year, age group and sex.
- Features for Prediction model : annual health checkup database including medical examination data related to diabetes, hyperlipidemia, hypertension and other health behavioral features were used to build the CVD prediction model.
- Algorithms of CVD prediction model: Logistic Regression, Decision Tree, Extra Tree, K-NN, Random Forest, Gradient Boosting, ADA Boosting, XG Boosting, Support Vector Machine, and Multi-Layer Perceptron.
- Feature importance: feature importance used for tree-based models and permutation importance supported by scikit-learn package are used.
- Performance comparison: ML algorithms improved the performance of CVD prediction, compared to the ACC/AHA risk model and the Framingham Risk Score.

## Note for performance matics and ML model settings

### 1. AUC-ROC

- predict() is used to predict the actual class (In your case one of 0, 1 or 1).
- predict\_proba() is used to predict the class probabilities
- The test in this code used predict\_proba() when calculating AUC-ROC values.

### 2. SVC v.s. . LinearSVC

Support Vector machine Classifier needs to set probability=True when model is made, in order to use predict\_proba function. LinearSVC does not support predict\_proba so if users want to get probability for the class, additional code like below needs to be considered.

```
from sklearn.svm import LinearSVC model = LinearSVC() model.fit(X,Y) Y = model.decision_function(X) prob
= (Y - Y.min()) / (Y.max() - Y.min()) print('Prob[0]: %.3f' % (1-prob[0])) print('Prob[1]: %.3f' % (prob[0]))
```

The above code can be used for only binary classification. Therefore, SVC is recommended in other cases than binary classification.
