## **Appendix 1. Detailed Search Methods.**

### *Literature Search*

This study was conducted in accordance with Preferred Reporting Items for Systemic Reviews and Meta-analysis (PRISMA) reporting guidelines<sup>1</sup> and the Diagnostic Test Accuracy extension.<sup>2</sup> The review protocol with minor adjustments was registered in <sup>3-37</sup>

We performed a systemic literature search from inception to August 1, 2022, and an updated search on August 17, 2023: PubMed/MEDLINE, Embase, Web of Sciences, and Cochrane Central Register of Controlled Trials (CENTRAL). Our search included the following search terms: biomarker, neurofilament light, NfL, NF-L, phosphorylated neurofilament heavy chain, pNfH, NF-H AND amyotrophic lateral sclerosis, and ALS. In addition to the database searches, we reviewed the reference lists of all included articles for potential eligibility. The database search was conducted by a National Institutes of Health Librarian/informationist.

### *Study Selection*

After the completion of all databases searches, all results were imported into citation management software EndNote 20 (Clarivate Analytics) and duplicates were removed. Next, the citations were exported into Covidence systemic review screening software (Veritas Health Innovations, Ltd.), Using Covidence, two reviewers (P.S. and G.C.) screened title and abstract to assess eligibility criteria and disagreements were resolved by consensus. Full text screening was conducted by (P.S. and G.C.) independently. Overall, there was an excellent agreement between the two reviewers (Cohen's  $\kappa = 0.93$ ).

### *Additional Exclusion Criteria*

We excluded conference proceedings and studies where we could not extract the data (e.g., figures could not be digitized), as well as studies where there was uncertainty regarding the demographic factors or biomarker concentration units.

## **Appendix 2. Data Inclusion for Studies with Duplicated Data.**

Data that were duplicated across more than one publication were not duplicated in our analysis nor included in our summary data in Table 1. However, duplicated data that reported their data in a different fashion, e.g., ROC curves or summary statistics versus association with disease progression may have contributed to different aspects of this meta-analysis. Publications with duplicated data are listed below:

Kojima *et al.*, 2021. *PLOS ONE*: overlap with Kasai *et al.*, 2019.

- Included the correlation between CSF NfL and ALSFRS-R score and disease progression.

## **Appendix 3. Outcome Assessment.**

The ALSFRS-R is a validated scale that measures physical function in carrying out activities of daily living in patients with ALS.<sup>38</sup> We extracted ALSFRS-R for assessing the relationship between functional outcome and neurofilaments. The ALSFRS-R is also used to monitor the progression of disability in patients with ALS. We included those studies where the ALS disease progression rate was calculated by subtracting baseline ALSFRS-R from 48 (maximum ALSFRS-R score), divided by time (months) from symptom onset to baseline.<sup>39</sup> This is a commonly reported estimate of disease progression. Studies that used the D50 disease progression model instead of ALSFRS-R were excluded from the meta-analysis of neurofilaments and disease progression. Publications using the D50 method<sup>40</sup> instead of ALSFRS-R are outlined below:

Dreger *et al.*, 2021. *Frontiers in Neuroscience*.

Poesen *et al.*, 2017. *Neurology*:

- Modeled disease progression using the D50 and ALSFRS-R score.

#### **Appendix 4. QUADAS-2.**

A quality assessment of all included studies was conducted using the revised tool for the Quality Assessment of Diagnostic Studies 2 (QUADAS-2)<sup>41</sup> to assess the risk of bias in each selected study. Two investigators (P.S. and C.G.) assessed all articles independently and discrepancies were resolved by consensus. The QUADAS-2 tool evaluated four bias categories: patient selection, index test, reference test, and flow of timing of testing. It also grades the risk that this bias decreases the applicability of the results in the target population. Studies that were considered at high risk of bias were not included in the analysis. Studies that did not report diagnostic test accuracy or the data was not available the QUADAS-2 was not applied.

#### **Appendix 5. Quantification of Plasma and Serum NfL.**

We undertook a subanalysis of the relationship between plasma and serum NfL and for this purpose we included 26 healthy controls (16 females and 10 males, mean age 23 years, SD 4.7) who had undergone paired plasma and serum sampling at Sahlgrenska University Hospital, Mölndal, Sweden. All participants provided written informed consent. Blood samples were collected by venipuncture into EDTA or serum tubes and centrifuged within 20-60 minutes. Plasma and serum samples were aliquoted and stored at  $-80^{\circ}\text{C}$  pending biochemical analysis. NfL was measured in plasma and serum using the Single Molecule Array technology (Quanterix, Billerica, MA, USA).<sup>42, 43</sup> All analytes had an average coefficient of variance  $<5\%$ . The comparison of NfL in plasma and serum has not been published previously.

#### **Appendix 6. Statistical Analysis.**

The statistical plan was developed together with two statisticians (G.N. and N.S.). For meta-analysis of diagnostic accuracy, we extracted area under the curve (AUC), sensitivity and specificity. Forest plots of sensitivity and specificity was performed. Meta-analyses for AUC were performed using R package *mada* (<https://rdrr.io/rforge/mada/src/R/reitsma.R>). For studies that reported AUC and not the sensitivity and specificity, authors were contacted to provide the sensitivity and specificity. For estimating a hierarchical summary receiver-operating characteristics curve, a bivariate modeling approach in *mada* was taken on the recommendation of the authors. Median concentrations and spread (interquartile range or range) and or mean (standard deviation) for each biomarker were extracted for available studies. We also performed

a meta-analysis of medians for each biomarker using the quantile estimation method (*metamedian* package in R statistical software).<sup>44</sup> Meta-analysis for correlation data was performed using R package *metacor* (<https://cran.r-project.org/package=metacor>). Only Spearman's rank correlations ( $r_s$ ) were used in the analysis due to the likely skewed nature of the data and since most studies reported Spearman's rank correlations. For studies that reported other correlation methods than Spearman, the corresponding authors were contacted to provide the Spearman correlations. In addition, we summarized overall study characteristics stratified by disease and controls. We pooled mean age using a weighted fixed effects model (*meta* package in R statistical software). In studies that reported age as median (IQR), the mean (SD) was estimated.<sup>45</sup> The variability in studies and/or patients for each comparison is a reflection of difference in data collection and reporting between studies; some studies reported ROC curve data and some studies reported group summary statistics as median (IQR) or mean (SD). For studies that reported log-transformed means, authors were contacted to provide median (IQR) and mean (SD). The relationship between the biomarkers and survival was assessed either using a univariate correlation (Spearman's rank correlation) between the serum biomarkers and survival time when data was available or based on reported hazard ratio (HR). Meta-analysis for survival data was performed using R package *metafor* (<https://CRAN.R-project.org/package=metafor>). Heterogeneity was assessed using the Cochran's  $Q$  test and the  $I^2$  index. Lastly, we performed sample size calculations two ways: (1) based on the pooled meta-analysis data, and (2) based on two studies with longitudinal follow-up data. As per Witzel *et al.*, NfL was demonstrated as an important prognostic biomarker for sample size estimations that reliably compensated for clinical heterogeneity. Further, Benatar *et al.* supported the preferential use of serum NfL over pNfH for implementation in future trials. To be thorough, we thus compared the sample sizes needed to detect intervention effects using NfL and pNfH measured in various fluid sources (plasma, serum, or CSF neurofilaments). The longitudinal data only used serum NfL; holding variance constant, sample sizes were estimated based on paired comparisons of expected change in NfL at ranging effect sizes. Effect sizes were calculated using Cohen's  $d$ .<sup>46</sup> We used the n80 criteria for assessing the efficiency of neurofilaments as outcome measures in future phase 2 ALS interventional trials.<sup>47</sup> The required sample size per calculation method assumed 80% power to detect a significant effect ( $\alpha = 0.05$ ) and varied as a function of putative

treatment effectiveness or effect size. All analyses were performed using R statistical software, version 4.0.4 (R Core Team).

Wilke et al. 2018 <sup>88</sup> PMID: 30009206	Prospective	Hereditary spastic paraplegia, ALS, and controls	Germany	Serum NfL	Simoa	225	Primarily a hereditary spastic paraplegia study that included ALS group for comparison
Zucchi et al. (2018) <sup>89</sup> PMID: 30428468	Prospective	ALS, primary lateral sclerosis, hereditary spastic paraplegia, and healthy controls	Italy	CSF and serum pNfH	ELISA	39	Primarily an upper motor syndrome study

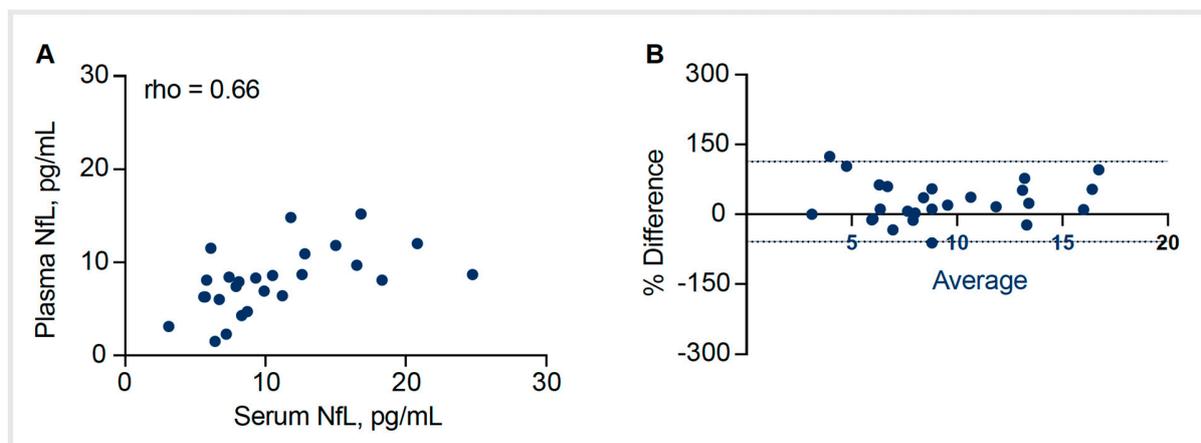

**Figure S1. Forest Plots and Receiver Operating Characteristics Curves for the Diagnostic Accuracy of Serum NfL.** Forest plots of sensitivity, specificity, and Summary Receiver Operating Characteristic (SROC) and their confidence intervals are presented. Each individual dot represents a unique study. The orange diamond represents the summary estimate of sensitivity and false-positive rate (1-specificity), and the dotted circle represents the 95% confidence region. On top of the SROC, “n” represents the total number of participants in the analyses.

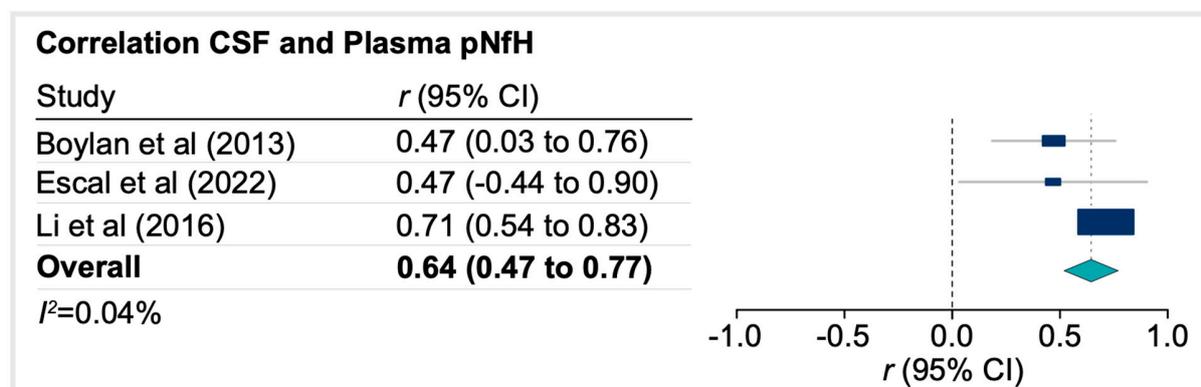

**Figure S2. Group Differences in Biomarkers Between ALS, ALS Mimic, and Controls.**

The pooled mean concentration and spread (confidence interval) are reported for NfL and pNfH in patients with ALS, ALS mimics, and controls.

**Figure S3. Correlation Plasma and Serum NfL.**

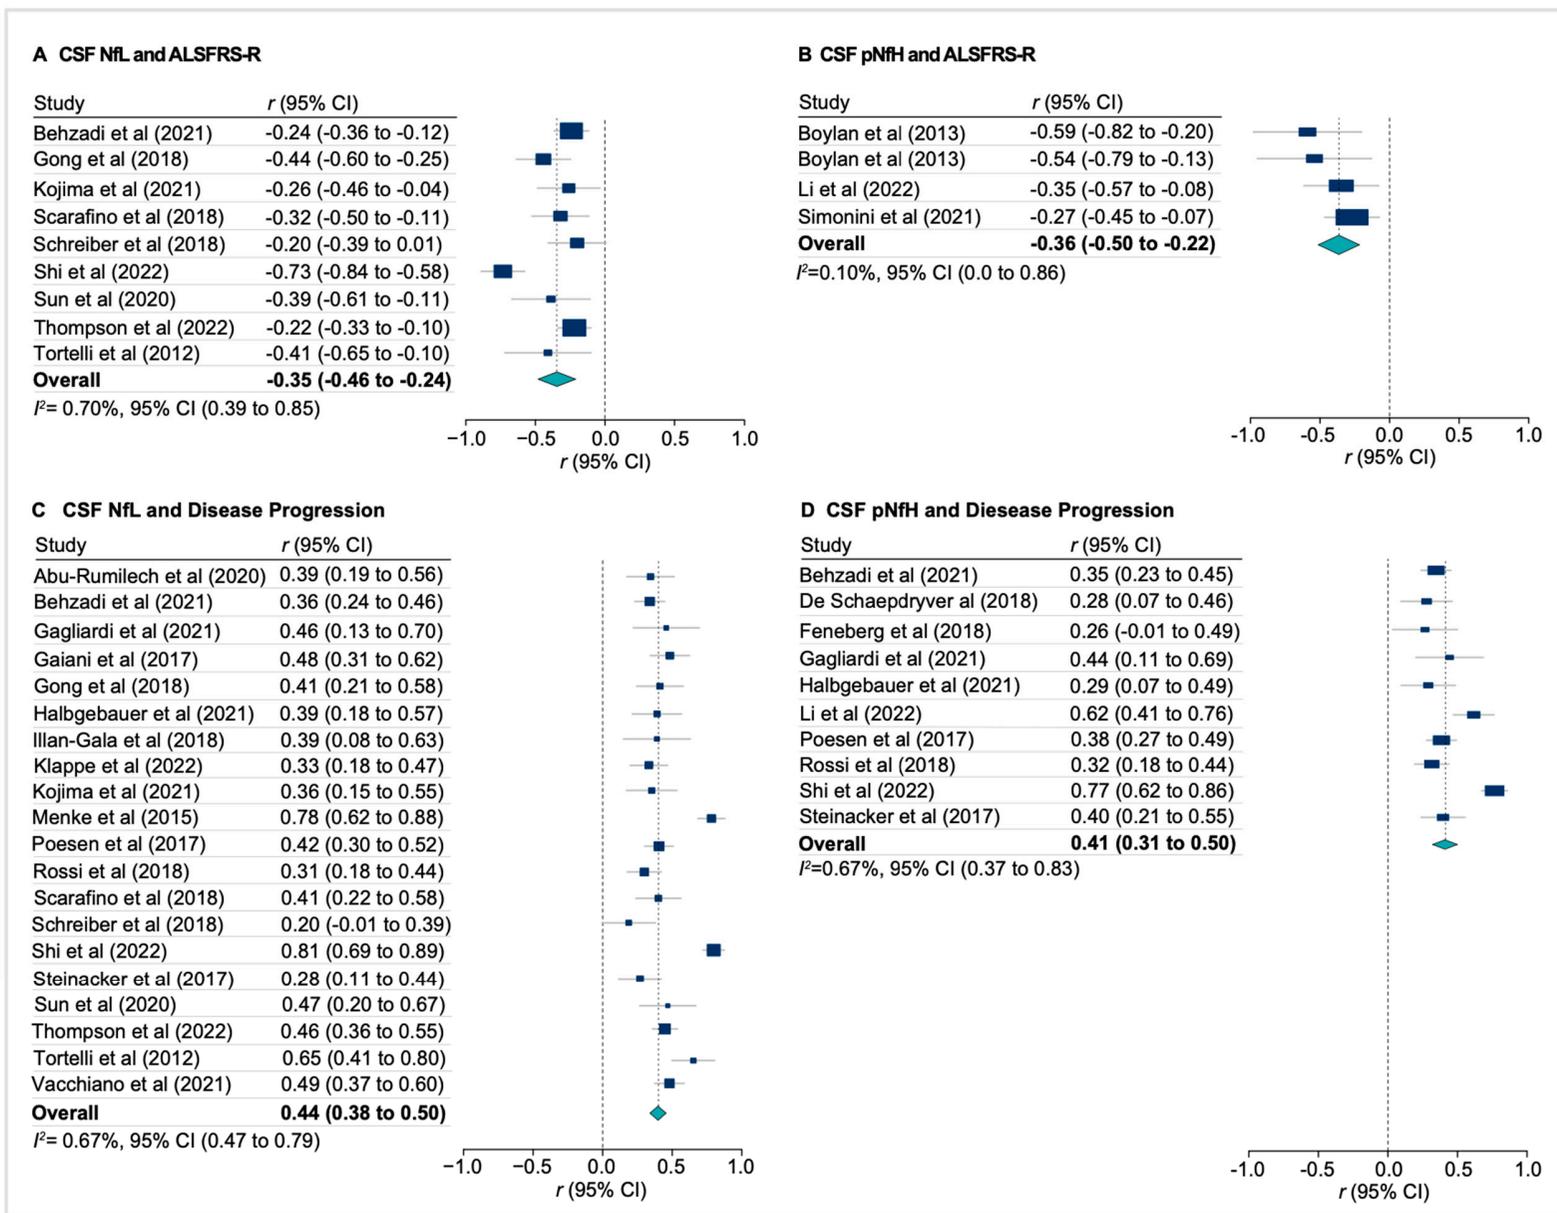

(A) shows the correlation between plasma and serum NfL. (B) shows the Bland-Altman agreement plot of the plasma and serum NfL. Single dots indicate NfL in plasma and serum with their mean concentrations on the x-axis and the difference in concentration between the two sources on the y-axis. The dashed horizontal lines indicate the upper and lower 95% confidence intervals for the mean difference between plasma and serum concentration.

**Figure S4. Meta-analysis of Correlation CSF and Plasma pNfH.**

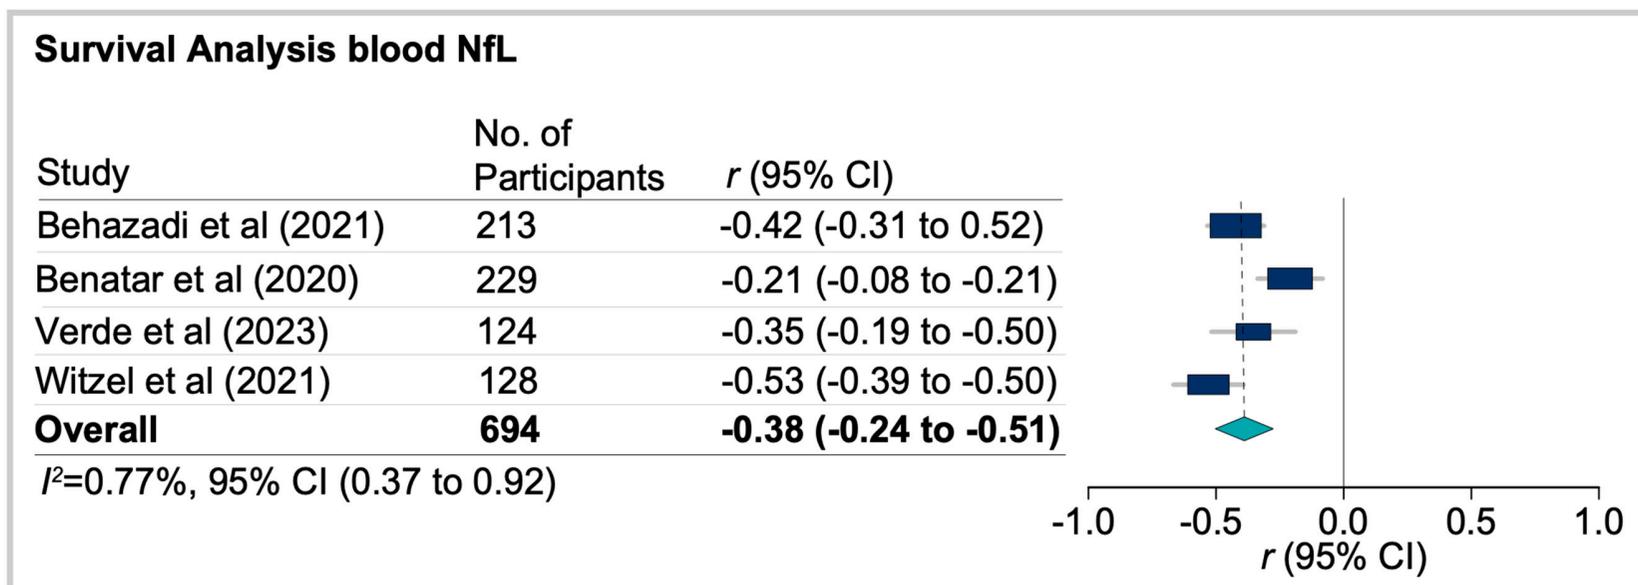

The correlations were calculated using the Spearman's rank correlation. Markers indicate estimates, with the size of the marker indicating weight; horizontal lines represent 95% CIs; diamond represent summary estimate, with the outer points indicating 95% confidence intervals.

<sup>o</sup>Mayo cohort (4 month)<sup>5</sup>

**Figure S5. Meta-analysis of Relationships of pNfH and NfL Measured in CSF and ALSFRS-R and Disease Progression. (A)**

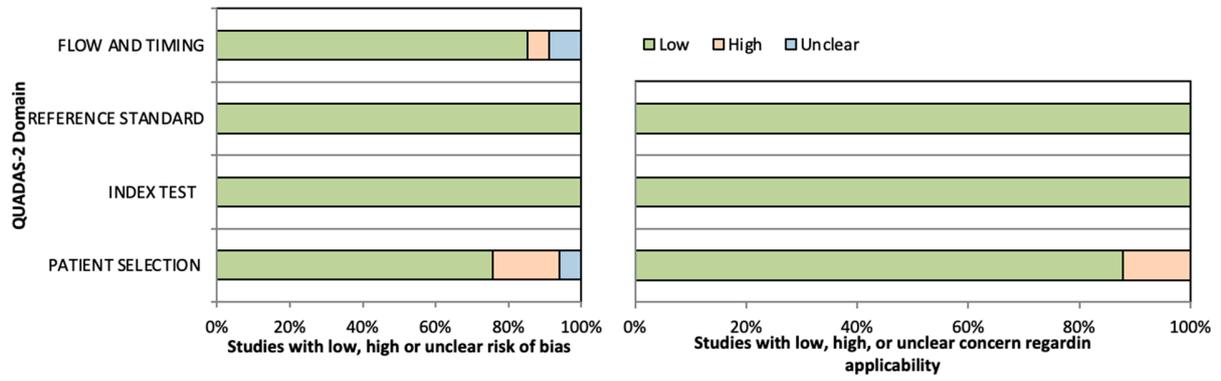

Correlation cerebrospinal fluid (CSF) NfL with ALS Functional Rating Scale (ALSFRS-R). **(B)** Correlation CSF pNfH with ALSFRS-R. **(D)** Correlation CSF NfL with disease progression. **(D)** Correlation CSF pNfH with disease progression. All correlations shown are Spearman's rank correlations. Markers indicate estimates, with the size of the marker indicating weight; horizontal lines represent 95% confidence intervals; diamonds represent summary estimates, with the outer points indicating 95% confidence intervals.

**Figure S6. Meta-analysis of Correlation Between Serum NfL and Survival Time.**

All correlations are Spearman's rank correlations. Markers indicate estimates, with the size of the marker indicating weight; horizontal lines represent 95% confidence intervals; diamonds represent summary estimates, with the outer points indicating 95% confidence intervals.

**Figure S7. Risk of Bias and Concerns for Applicability Assessment**

<b>Table S3. Sample Size Per Group for Various Effect Estimates</b>			
Treatment Effectiveness (%)	Sample Size Per Group	Outcome	Cohen's <i>d</i>
10	137	CSF NfL	3.4
15	61	CSF NfL	3.4
20	34	CSF NfL	3.4
25	22	CSF NfL	3.4
30	15	CSF NfL	3.4
35	11	CSF NfL	3.4
