

## Supplementary figures

**Supplementary Figure S1. STAU1<sup>55</sup> is tagged by K11-ubiquitin chains.** HEK293T cells were co-transfected with plasmids coding for STAU1<sup>55</sup>-HA<sub>3</sub> (STAU1) or deletion mutants and for GFP-ubi (+) (A) or GFP-ubi-K11R (+) (B). Cells expressing GFP-ubi or GFP-ubi-K11R were further incubated in the presence (+) or absence (-) of MG132 for 8 h. Protein extracts were analyzed by western blotting using anti-HA (to detect STAU1) and anti-GFP (to detect total protein ubiquitination) antibodies. The blots are representative of three independently performed experiments that gave similar results.

**Supplementary Figure S2. In silico modelling of the FPL-motif.** (A) In silico modelling (I-Tasser software) of the RBD2 domain with the position of amino acids of the FPL-motif. While the predicted alpha helices ( $\alpha 1$  and  $\alpha 2$ ) and the beta sheaths ( $\beta 2$  and  $\beta 3$ ) of RNA-binding domains are conserved, the beta sheath  $\beta 1$  is disordered in the modelling. The FPL-motif is located in the loop between the disordered region and  $\beta$ -sheath 2 (Phe<sup>39</sup>, Pro<sup>40</sup>, Pro<sup>42</sup>, Leu<sup>45</sup>) and in the beta sheath  $\beta 2$  (Leu<sup>50</sup>). (B-M) Amino acid conservation of the FPL-motif through evolution. Blue columns: amino acids required for the function of the FPL-motif.  
Homo, humans. Macaca, macaques. Rattus, rats. Mus, mice. Bos, cattle. Canis, dog. Xenopus, frogs. Gallus, chicken. Danio, zebrafish.
