

Supplementary Figures

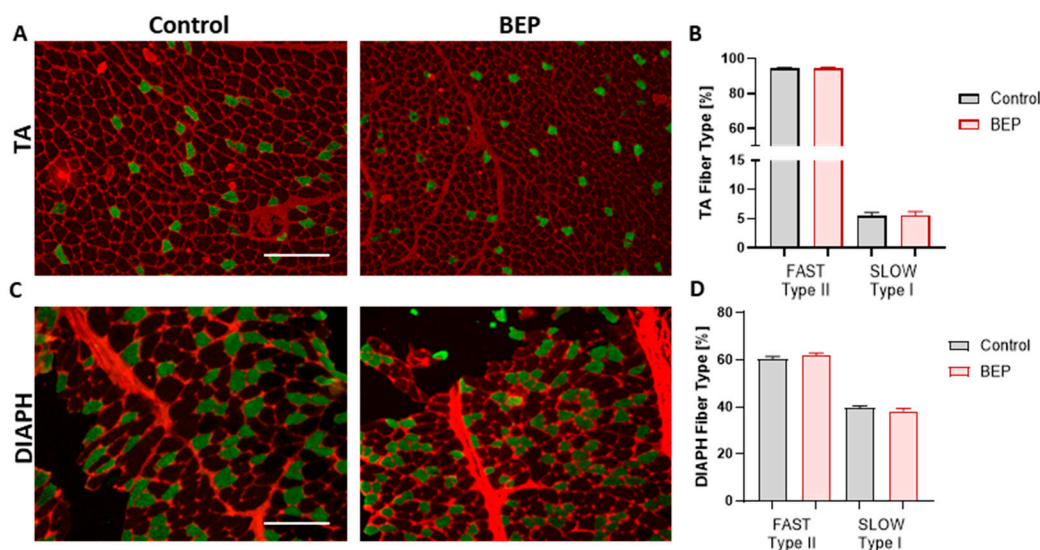

Supplementary Figure S1. Binge-like ethanol protocol decreases muscles weight. Muscle weight of TA (A), EDL (B), Gastrocnemius (C), and soleus (D). E-G. The relative weight of EDL, Gastrocnemius (F), and soleus (G). Relative weight was determined by normalizing the weight of muscles to the weight of control muscles. Graphs represent mean \pm SEM. N Control = 2 N BEP = 4. * $p \leq 0.05$; ** $p \leq 0.01$.

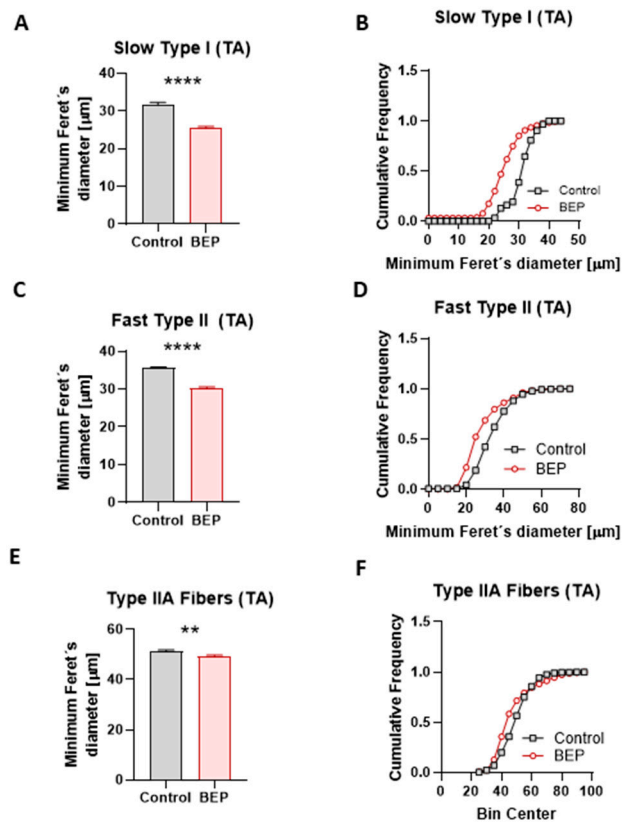

Supplementary Figure S2. Binge-like ethanol protocol does not alter muscle morphology. A, B, C and D. Representative images of hematoxylin eosin stained muscle sections of TA (A), DIAPH (B), EDL (C) and Soleus (D). Scale bar 100. Control N= 6, BEP N= 4.

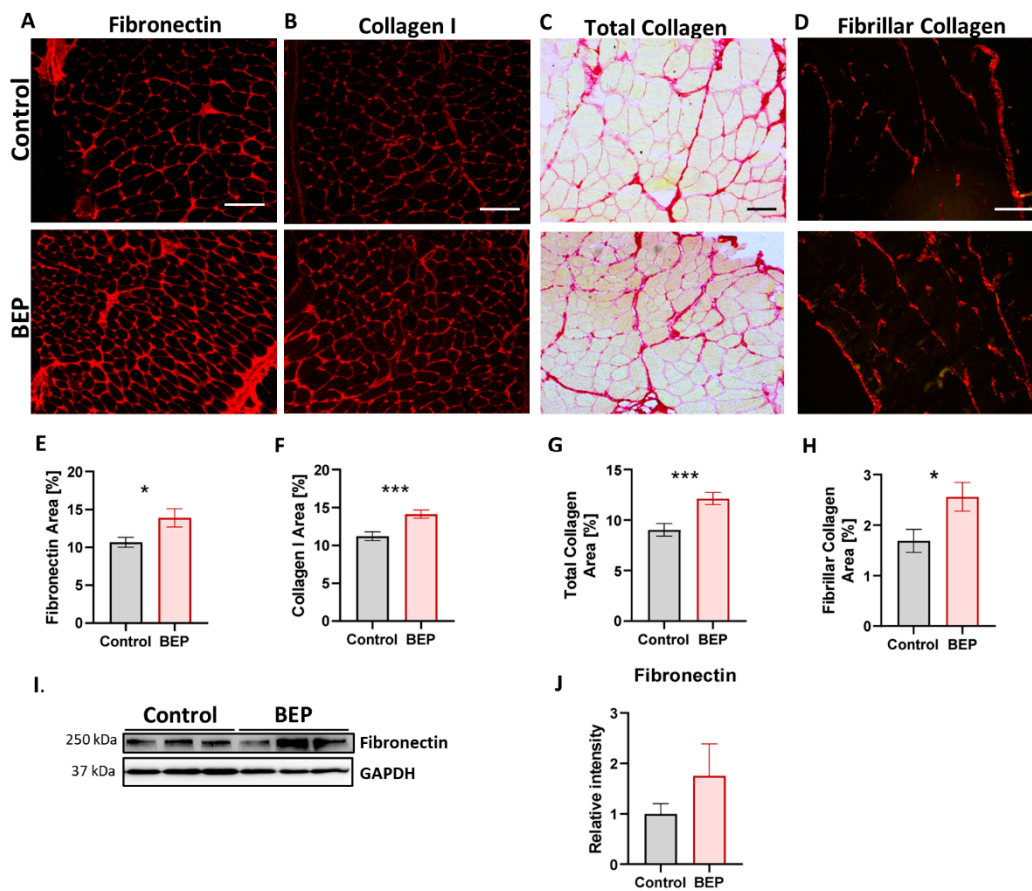

Supplementary Figure S3. Binge-like ethanol protocol induces skeletal muscle atrophy. **A.** Immunoblot of Atrogin-1, and GAPDH as a loading control, and densitometric quantification on TA muscle. Control N=4, BEP N=4. **B.** Representative image of WGA-stained muscle sections of EDL. Scale bar 100 μm . **C.** Quantification of minimum Feret's diameter of skeletal muscle fibers of EDL. Control N=3, BEP N=2. Graphs represent mean \pm SEM, 7 images per N. **D.** Histogram showing relative frequencies of minimum Feret's diameter in EDL. **E.** Histogram showing cumulative frequencies of minimum Feret's diameter in EDL. Graphs represent mean \pm SEM. **** $p \leq 0.0001$.

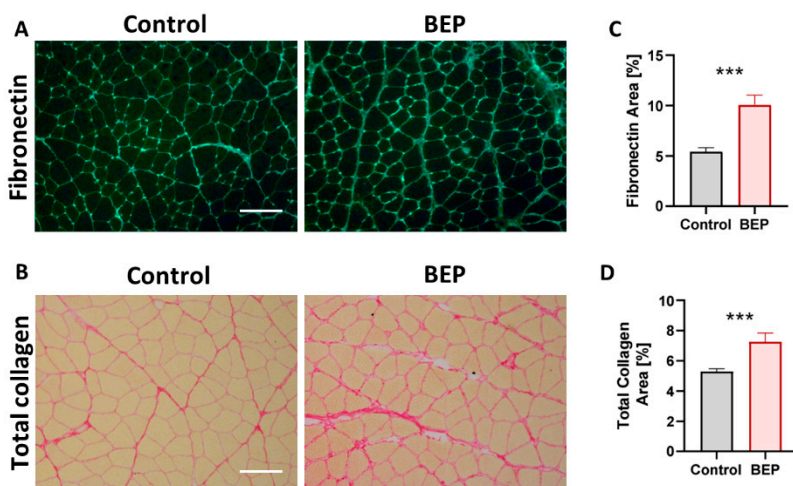

Supplementary Figure S4. Binge-like ethanol protocol does not alter muscle fiber type proportion. **A, C.** Representative images of TA (A) and DIAPH (C) immunofluorescence using WGA (red) and anti- Slow Myosin antibody (green). Fibers stained in green correspond to slow type I fibers, and non-stained fibers in black correspond to fast type II fibers. Scale bar: 100 μm . **B, D.** Percentage of fiber types on TA (B) and DIAPH (D). Control N=5, BEP N=6.

Supplementary Figure S5. Binge-like ethanol protocol induce atrophy independent of skeletal muscle fiber type. A, C, E. Quantification of minimum Feret's diameter of slow type I (A), fast II type (C) and type IIA (E) skeletal muscle fibers of TA. Control N=3, BEP N=2. F, I. Histograms showing cumulative frequencies as fraction of minimum Feret's diameter of slow type I (B), fast II type (D) and type IIA (F) skeletal muscle fibers of TA. Control N=3, BEP N=2. ** $p \leq 0.01$; **** $p \leq 0.0001$

Supplementary Figure S6. Binge-like ethanol protocol induces ECM protein accumulation and enhances fibrotic markers on DIAPH muscle. **A, B.** Representative images of DIAPH immunofluorescence using anti-fibronectin (**A**) and anti-collagen I (**B**) antibodies. **C, D.** Representative images of Sirius Red staining in brightfield microscopy showing total collagen (**C**) and polarized light microscopy showing fibrillar collagen (**D**). Scale bar 100 μ m. **E-H.** Quantification of fibronectin (**E**), collagen I (**F**), total collagen (**G**), and fibrillar collagen (**H**) as a percentage of occupied area fraction. Control N=5, BEP N=6. **I.** Immunoblot against fibronectin and GAPDH as a loading control. **J.** Densitometric quantification of immunoblots against fibronectin. Control N=4, BEP N=4. * $p \leq 0.05$; *** $p \leq 0.001$.

Supplementary Figure S7. Binge-like ethanol protocol induces ECM protein accumulation on EDL and soleus muscle. **A.** Representative images of EDL immunofluorescence using anti-fibronectin antibody. **B.** Representative images of Sirius Red staining in brightfield microscopy showing total collagen in soleus. **C, D.** Quantification of fibronectin (**C**) and total collagen (**D**) as a percentage of occupied area fraction. Control N=3, BEP N=2. Graphs represent mean \pm SEM, 7 images per N. Scale bar 100 μ m. *** $p \leq 0.001$.
