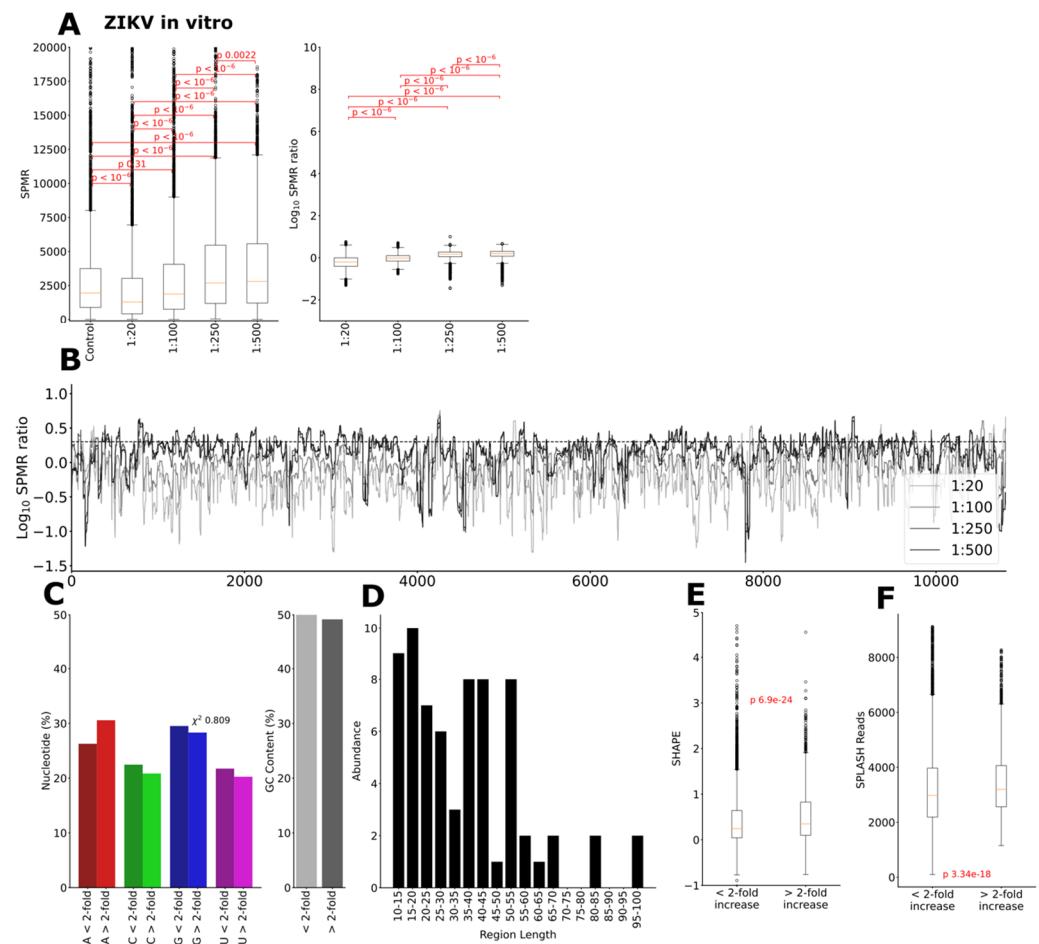

Figure S1. ZIKV C protein data. Abundance of (A) reads after SPMR normalization in ZIKV and ratio of read abundance over control show that at a molar ratio of 1:250 the genomes are saturated with C protein, indicating that the saturation point lies at or below this level. (B) Localization of binding signal along the ZIKV genome for *in vitro* transcribed genomic RNA. (C) The nucleotide composition and GC content of C protein binding locations is not significantly different from non-binding locations. (D) Average length of interacting segments shows multimodal distribution consistent with clusters of fixed-length interactions. (E) Binding *in vitro* preferentially occurs in higher SHAPE reactivity, single-stranded, and open regions of the viral genome. (F) ZIKV C shows *in vitro* preference for regions of long-range intramolecular RNA-RNA interactions, as measured by SPLASH.

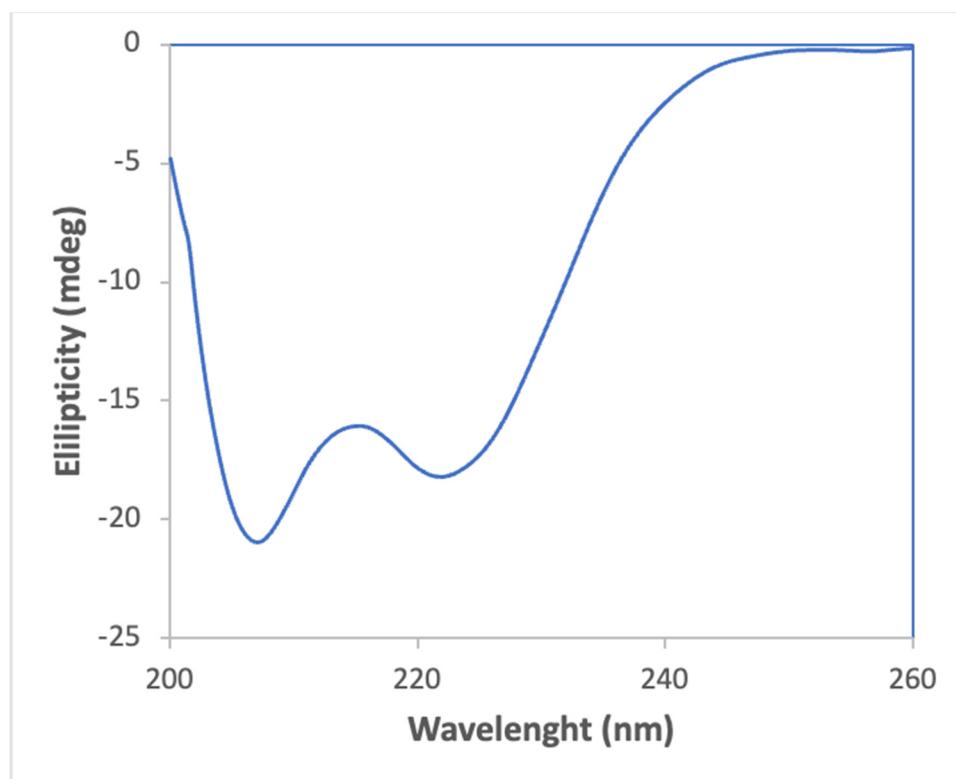

Figure S2. CD spectra obtained for ZIKV C protein at 25 °C. A typical spectrum for an α -helix secondary structure is obtained for ZIKV C protein at 25 °C (black line), as expected. CD measurements were performed as previously described for DENV C (Faustino et al. *Int J Mol Sci* 20 (2019) 3870. doi:10.3390/ijms20163870), in 50 mM KH₂PO₄, 200 mM KCl, pH 7.5 buffer, at 25 °C.

Table S1. Overview of samples, conditions and number of aligned reads per sample.

Experiment	Condition	Sample	Aligned Reads
