[a] Drug-gene pairs in bold are those with the 10 highest PDCs in the study; drug-gene pairs in italics are those with the 10 lowest PDCs in the study.

[b] CPIC Level A indicates: "Genetic information should be used to change prescribing of [the] affected drug. Preponderance of evidence is high or moderate in favor of changing prescribing. At least one moderate or strong action (change in prescribing) [is] recommended." CPIC Level A/B indicates: "Preliminary review indicates it is likely that the definitive CPIC level will be either A or B. Full evidence review [is] needed to assess level of evidence, but prescribing actionability is likely. Full review by expert guideline group [is needed] to assign strength of recommendation." CPIC level B indicates: "Genetic information could be used to change prescribing of the affected drug because alternative therapies/dosing are extremely likely to be as effective and as safe as non-genetically based dosing. Preponderance of evidence is weak with little conflicting data. At least one optional action (change in prescribing) is recommended." [5]
