Chemical Structures

Figure S1. Dyads and triads already investigated by some of us

Figure S2. Synopsis of chemical structures

Experimental

General Methods. ^1H -NMR spectra were recorded as CDCl_3 and C_6D_6 solutions on a Bruker AM-300 instrument using residual solvent signal as an internal standard. Chemical shifts are given as δ values. FAB mass spectra were measured on a VG-4 spectrometer using m-nitrobenzyl alcohol (NBA) as a matrix. Matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) mass spectra were performed with a MALDI-TOF Reflex IV instrument (Bruker-Daltonics) in reflector mode, using a 337 nm nitrogen laser (8 Hz). A 2 mg/mL 2,5-dihydroxybenzoic acid (gentisic acid) solution in CH_3CN /TFA (0.1% solution) was used as a matrix. Electronic absorption spectra were recorded in CH_2Cl_2 solution at room temperature on a Shimadzu UV 3600 spectrophotometer (Shimadzu Corporation, Kyoto, Japan).

Raman spectra were obtained by using a confocal Raman microscope Invia Renishaw, endowed with a 633 nm laser, a RenCam CCD detector, 1024x256 pixels (200-1060 nm), an encoded xyz stage (replacement precision: 100nm), using an 1800 l/mm grating.

XPS measurements were obtained from a modified Omicron NanoTechnology MXPS system. The spectra were excited by achromatic Mg K α and Al K α photons ($h\nu = 1253.6$ and 1486.6 eV, respectively), generated operating the anode at 14-15 kV, 10-20 mA. All the samples were mounted on metal tips as thin layers of pressed powders. Experimental spectra were theoretically reconstructed by fitting the peaks to symmetric pseudo-Voigt functions (linear combination of gaussian and lorentzian peaks) and the background to a Shirley or a linear function. XPS atomic ratios ($\pm 10\%$ associated error) between relevant core lines were estimated from experimentally determined area ratios corrected for the corresponding theoretical cross sections and for a square root dependence of the photoelectron's kinetic energies. All binding energies were referenced to the lowest lying C 1s peak component, taken at 285.0 eV, which was assumed to be related to the aromatic C atoms

Elemental analyses were carried out with a PerkinElmer CHN 2400 instrument in the Analytical Laboratories of the Department of Chemistry at the University of Milan.

Mass spectrometry and ^1H -NMR spectroscopy

FAB spectrum of P-CHO

Figure S3. FAB spectrum of compound P-CHO using as matrix NBA

^1H -NMR spectrum of P-CHO

^1H -NMR (300 MHz, CDCl_3): δ (ppm) 10.06 (s, 1H), 9.10 (s, 1H), 8.90 (s, 2H), 8.85 (d, 3J) 5.9 Hz, 1H), 8.79 (s, 2H), 8.77 (d, 3J) 5.9 Hz, 1H), 8.23 (br m, 5H), 7.91 (d, 3J) 7.8 Hz, 2H), 7.80-7.66 (br m, 17H), 7.54 (d, 3J) 7.8 Hz, 2H), 7.38 (d, 2H; J) 7.8), -2.65 (s, 2H).

X-Ray Photoelectron spectroscopy

Compound ZnP-GNP

In Figures S10a and S10b the N 1s and Zn 2p_{3/2,1/2} photoemission regions for **ZnP-GNP** are reported (Fe is not present in the compound).

The two N 1s distinct components shown in Figure S10a confirm the functionalization of the Zinc 2-[(4'-formyl)phenyl]ethynyl-5,10,15,20-tetraphenylporphyrin on graphene surface. The first peak was attributed to porphyrin nitrogens (399.4 eV) and the second to substituted amine group (402.4 eV) with a 4.0 atomic ratio of the first to the second component. In Figure S10b the Zn 2p_{3/2,1/2} component shows a peak at 1022.4 eV, confirming the insertion of the zinc in the macrocycle.

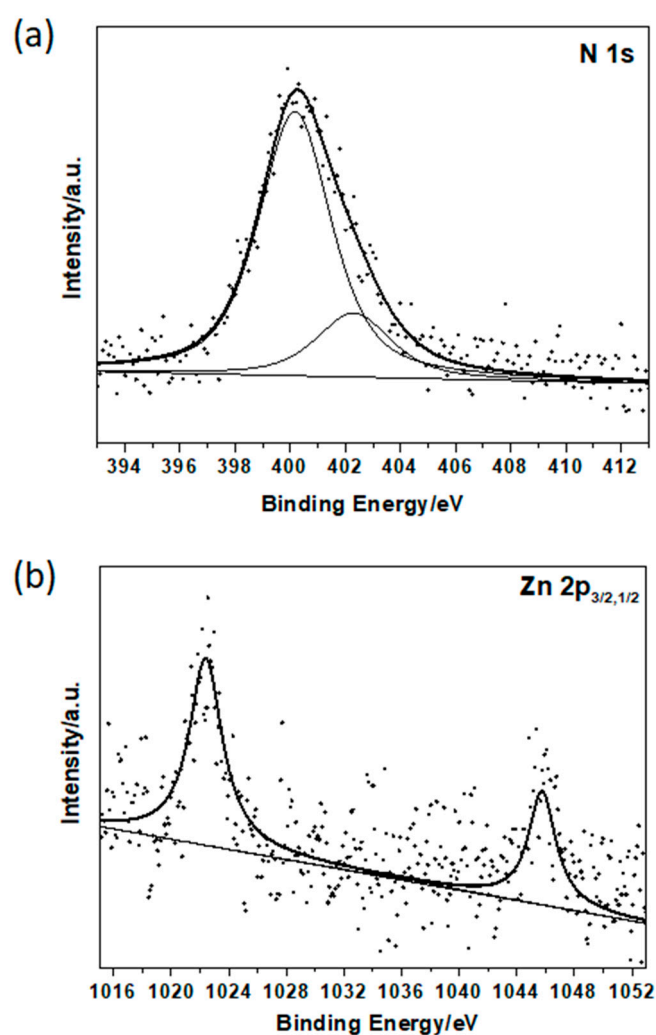

Figure S12. (a) N 1s and (b) Zn 2p_{3/2,1/2} photoemission regions of **ZnP-GNP**. Experimental curve (dots) and peak-fit components (lines) are shown together

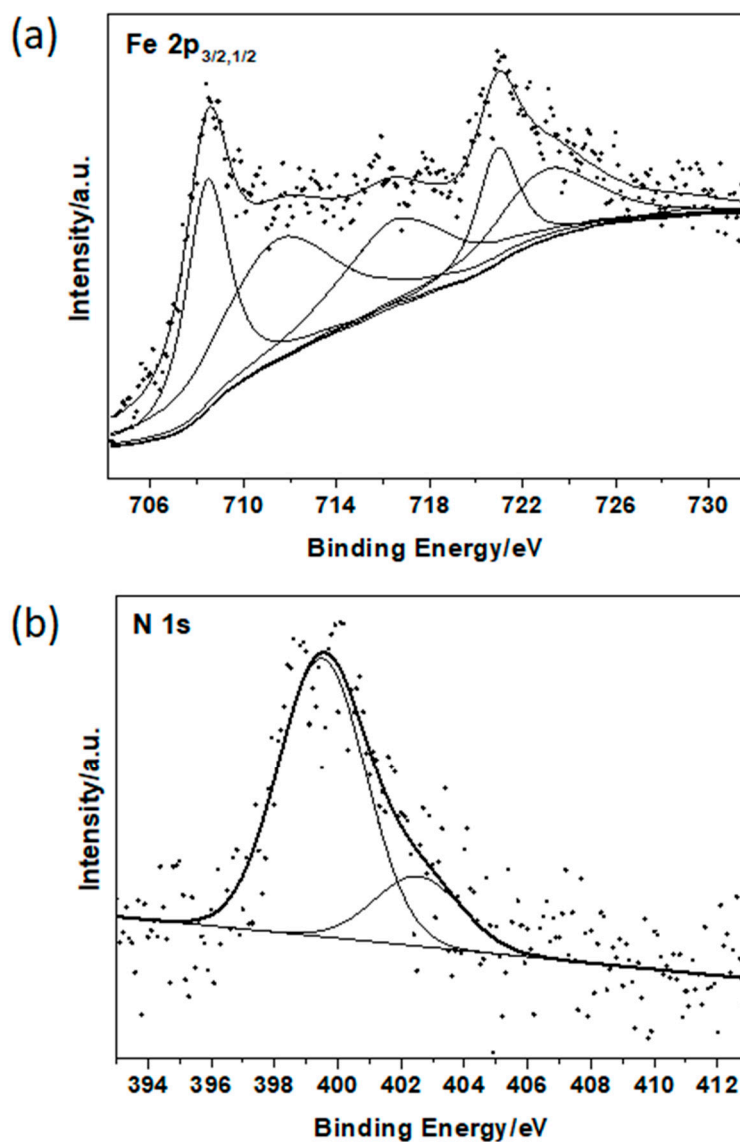

Figure S13. (a) Fe 2p_{3/2,1/2} and (b) N 1s photoemission regions of Fc-ZnP-GNP. Experimental curve (dots) and peak-fit components (lines) are shown together.
