The ECD computational detail of compound **3**

Conformational searches were done using Molecular Merck force field (MMFF) embedded in Spartan'14 software (Wavefunction Inc., Irvine, CA, USA). Density functional theory (DFT) and time-dependent density functional theory (TDDFT) calculations were performed with Gaussian09 RevD.01. [26]. Double-hybrid (DH) DFT calculations were conducted with ORCA 4.2.1 program package using RIJK approximation, tight SCF criteria, and grid 6 integrity [27]. For simulations of ECD spectrum of compound **3**, low-energy conformers of (1R,2S,6S,10R,13S)- and (1R,2S,6S,10S,13R)-**3** within a 10 kcal/mol energy window from MMFF conformational search were subjected to geometry optimizations followed by frequency calculations using DFT method at the B3LYP [28,29] /Def2-SVP [30] level of theory with the solvent model PCM for MeOH. The

high level of single point calculations of the optimized low-energy conformers was carried out using the DH-DFT method at the PWPB95 [31] -D3BJ [32,33] / def2-QZVPP[29]. level with the SMD [34] solvent model for MeOH. The TDDFT calculations were carried out using PBE1PBE (PBE0) [35] , M06 [36] and M06-2X [37] functionals in combination with the TZVP [38]. basis set and the PCM solvent (MeOH) model. The number of excited states was 20 for all conformers. The results were visualized and exported using the SpecDis program [39]. The calculated ECD spectra of the two stereoisomers were generated as a sum of Gaussian curve with the σ value of 0.27 eV using rotatory strengths computed in the dipole-velocity gauge from ECD data of the individual low-energy conformers. Boltzmann distributions of the conformers in equilibrium population were estimated from the relative Gibbs free energies (ΔG) at 298.15K.
