Measurement of mechanical properties of cryogel by dynamic mechanical analyzer (DMA)

Before the compression test, the cryogels were immersed in distilled water for 15 min to achieve equilibrium swelling. Compression tests were performed using a tension compression test machine (DMA Q800 V21.3 Build 96) using samples of cylindrical shape (~10 mm diameter and ~10 mm height). Samples were compressed with two parallel plates at the maximum loading of 0.01 N with a compression rate of 1 mm/min. The stress, strain (%), and toughness values were calculated by the Trapezium X Materials Testing Software (Shimadzu, Japan). The compressive modulus was calculated from the linear region of the stress-strain curve (0–25% strain).

Cyclic voltammetry (CV)

CV measurements were done in three-electrode cell configuration in the potential window from -0.1 V to 0.8 V vs Ag/AgCl (3M KCl) reference electrode in 0.1 M H₂SO₄ with the scan rate from 10 mV/s to 150 mV/s.
