Abstract: Environmental pollution is a major threat to public health and is the cause of important economic losses worldwide. Atmospheric nitrogen deposition is one of the most significant components of environmental pollution, which, in addition to being a health risk, is one of the leading drivers of global biodiversity loss. However, monitoring pollution is not possible in many regions of the world because the instrumentation, deployment, operation, and maintenance of automated systems is onerous. An affordable alternative is the use of biomonitoring, naturally occurring or transplanted organisms that respond to environmental pollution with a consistent and measurable ecophysiological response. This policy brief advocates for the use of biomonitoring of atmospheric nitrogen deposition. Descriptions of the biological and monitoring particularities of commonly utilized biomonitor lichens, bryophytes, vascular epiphytes, herbs, and woody plants, are followed by a discussion of the principal ecophysiological parameters that have been shown to respond to the different nitrogen emissions and their rate of deposition.

Keywords: atmospheric pollution; environmental management; epiphytes; grasses; mosses; planetary boundaries; policy; public health.

1. A systematic literature review of biomonitoring of nitrogen deposition

The biomonitoring synthesis from the main text was conducted from a systematic literature review based on searches in the Scopus database (Elsevier, Amsterdam) complemented with relevant articles identified as relevant from the authors' collective experience (Figure S1). We searched for papers containing the phrases "biomonitor(s)", "nitrogen deposition", and "nitrogen/NO_x/ammonium/ammonia emissions". We focused on works that evaluated physiological traits of autotrophic organisms in response to Nitrogen emissions and deposition. Papers dealing primarily with population biology were excluded, as well as those focusing on types of pollution including aquatic pollution and heavy metals.

We identified 63 articles that utilized the physiological responses of autotrophic organisms with potential for biomonitoring nitrogen deposition (Figure S2; Table S1). While bryophytes were the most utilized lifeform for biomonitoring (26 studies), biomonitoring has also been conducted with lichens (mostly utilized as bioindicators), ferns, vascular epiphytes (especially two species in the neotropical genus *Tillandsia*), herbs, and woody plants (Figure S2a). The studies considered a combined total of 247 biomonitoring species, the most numerous being woody plants (Figure S2b).

Most of the articles reported were field studies, while only 10% were conducted under controlled environmental conditions, usually to calibrate plant responses to (simulated) nitrogen pollution. The parameters that were most sensitive to nitrogen deposition included the nitrogen elemental and isotopic status of biomonitor, photosynthesis indicators (chlorophyll and accessory pigment concentration and chlorophyll fluorescence), the activity of enzymes related to the nitrogen metabolism and with oxidative stress protection (Table S1).

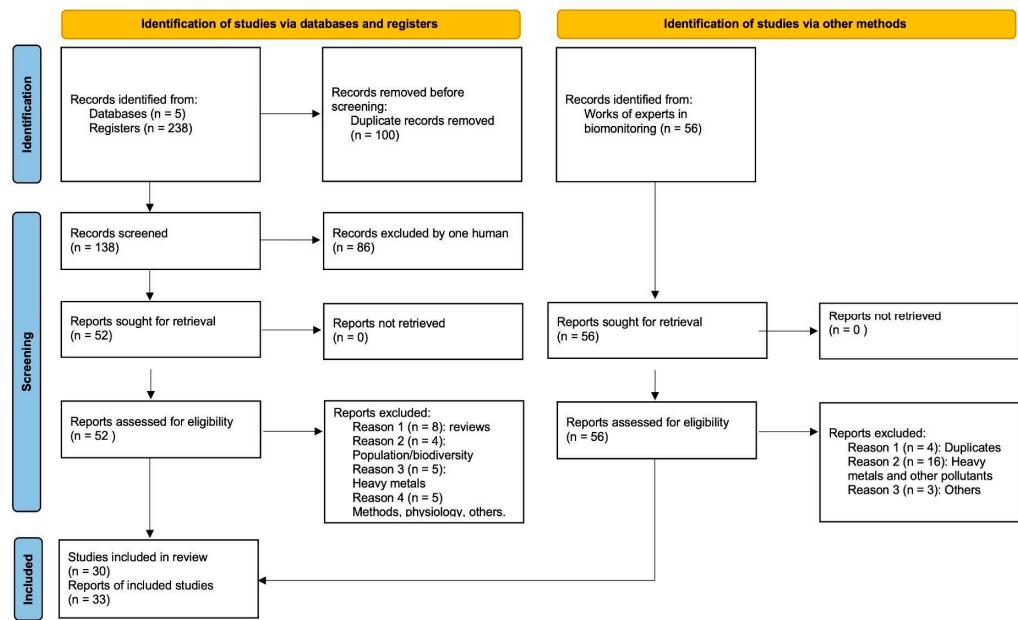

Figure S1. PRISMA [90] flow diagram for the systematic literature review conducted for biomonitoring of nitrogen deposition.

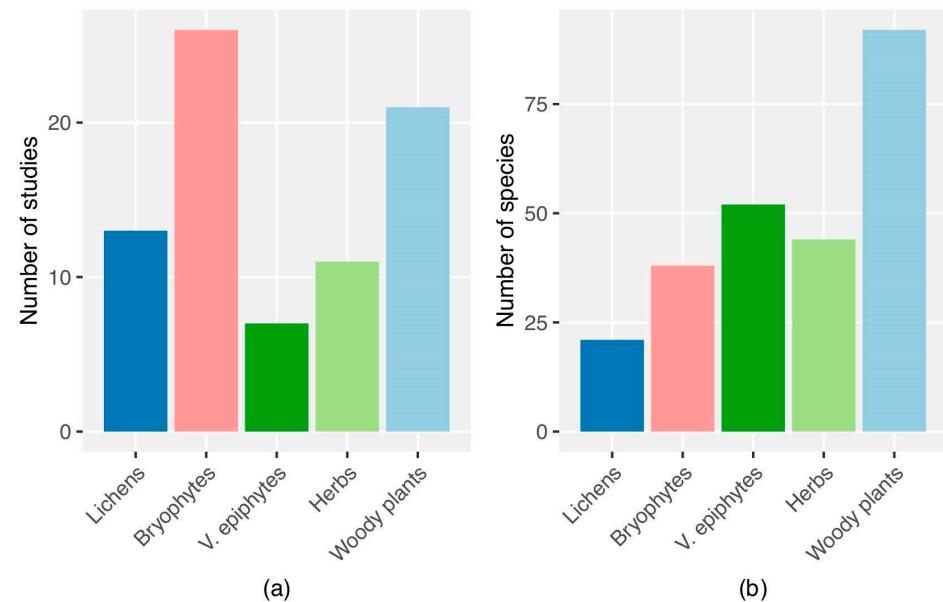

Figure S2. Number of studies identified in the literature review that utilized different biomonitor lifeforms (a) and total number of species per lifeform reported in the literature (b).

Table S1. Biomonitor of nitrogen deposition identified in the systematic literature review. Species and physiological traits analyzed under pollution gradients (field) or under with controlled environmental conditions of N pollution (Ctrl. cond.). N%, N elemental content; N/P and C/N, ratios of nitrogen with phosphorus and carbon; Protein, protein content; a.a, amino acids; ChlT, total chlorophylls; Chl *a/b*, ratio chlorophyll *a/b*; Neo+Lut/β-Car, neoxanthin + lutein/β-carotene; F_v/F_m, Fluorescence of chlorophyll *a*; @PSII, quantum efficiency of photosystem II; NQP_{max}, non-photochemical quenching; K, content of potassium; MDA, malondialdehyde; NR, nitrate reductase activity; NiR, nitrite reductase activity; GS, glutamine synthetase activity; PME, phosphomonoesterase activity; SOD, superoxide dismutase activity; POD, peroxidase activity; PPO, polyphenol oxidase activity; DHA, dehydrogenase activity. Reference numbers correspond to those in the main text.
