Message from the Guest Editor

The production of solid waste accompanies the development of human society, upon which it has a serious negative impact. The treatment and disposal of solid waste is faced with many challenges due to its large quantity and varying nature. With the increase in population and the aggravation of natural resource constraints, ensuring the harmless treatment and resource utilization of solid waste has become a direction of future development.

The purpose of this Special Issue is therefore to disseminate the results of research into bio-based solid waste treatment and management. Particular attention will be given to those studies that address organic solid waste biotreatment, organic waste to biochar, and nanotechnology applications in solid waste treatment.
