Message from the Guest Editors

Dear Colleagues,

Climate models are widely used to understand and predict the evolution of the climate system. They use quantitative methods to simulate the interactions of the important drivers of climate, including astronomical conditions as well as atmosphere, oceans, land surface and ice.

Although climate models have been improving in accuracy and efficiency over the past few decades, they still represent a complex endeavor and, due to the large number of involved processes and the interactions among them, spread across climate projections for given future scenarios persist. For these reasons, there is an urgent need to improve their accuracy to provide more confident assessments of the future risks associated with both natural climate variability and human-induced climate change.

Therefore, we welcome the submission of papers covering any aspects of the application of climate models and achievements in accuracy improvement in climate modelling.
