Medication Related Osteonecrosis of the Jaw: What We Know

Message from the Guest Editors

Medication-related osteonecrosis of the jaw (MRONJ) is a side-effect of several drugs, often linked with antiresorptive agents in different therapies such as for cancer, osteopenia, and Paget disease.

This condition involves different medical fields, from oncology and general medicine, to dentistry and maxillo-facial surgery. Nowadays, there are attempts to increase the knowledge about new molecules related to MRONJ in order to expand medical operators' awareness, with the main goal being to prevent the onset of the problem. Concurrently, treatment options are not fully defined and seem to have the same complex management of the onset prevention. Since further studies are needed to find a correct path to manage these complex cases, case series, case report and papers about personal own experience in all stages of the disease are recommended. In this light, and with the aim to promote a better knowledge and awareness of this pathology, articles addressing these topics are warmly invited to this Special Issue.

About the Journal

Message from the Editor-in-Chief

Addressing the environmental and public health challenges requires engagement and collaboration among clinicians and public health researchers. Scientific discoveries and advances in this research field play a critical role in providing a rational basis for informed decision-making toward control and prevention of human diseases, especially the illnesses that are induced from environmental exposure to health hazards.

IJERPH provides a forum for discussion of discoveries and knowledge in these multidisciplinary fields. Please consider publishing your research in this high quality peer-reviewed journal.
