Infectious Diseases in Beneficial Insects: Current Status of Pébrine and Nosema Diseases and Their Progression (2nd Edition)

Message from the Guest Editors

Beneficial insects have been treated with great care since ancient times because they provide various beneficial substances for humankind. They suffer from disease, similarly to humans. In particular, silkworm pébrine, a microsporidiosis caused by infection with microsporidia, is considered to be the most serious because of its chronic pathogenicity. The microsporidian parasite is transmitted from the mother moth to the next generation through the eggs, making it difficult to eliminate the disease. Although the pébrine has been prevented using the prophylactic method of mother moth examination, which was invented by Pasteur, the disease has not yet been eradicated. Additionally, honeybee nosemosis (microsporidiosis caused by microsporidia belonging to the genus *Nosema*) continues to be detected all over the world. Microsporidiosis remains a persistent threat to sericulture and apiculture.

This Special Issue welcomes review and research article papers focusing on the occurrence, distribution, and biological aspects of microsporidiosis in beneficial insects, silkworms, and bees since 2000.

About the Journal

Message from the Editor-in-Chief

Editor-in-Chief

Prof. Dr. Brian T. Forschler

Department of Entomology, University of Georgia, 413 Biological
Sciences Building, Athens, GA 30602-2603, USA

Author Benefits

High Visibility:

indexed within Scopus, SCIE (Web of Science), PubMed,
PMC, PubAg, and other databases.

Journal Rank:

JCR - Q1 (Entomology) / CiteScore - Q1 (Insect Science)

Rapid Publication:

manuscripts are peer-reviewed and a first decision is
provided to authors approximately 18.1 days after
submission; acceptance to publication is undertaken in 2.9
days (median values for papers published in this journal in
the first half of 2025).
