### Message from the Guest Editor

Dear Colleagues,

A high-fat diet and less physical activity result in a higher energy intake and lower energy expenditure. High-fat diets, which are frequent related to obesity, are associated with many health problems, including cognition, cardiovascular and metabolic issues, non-alcoholic fatty liver disease and even cancer. However, which populations are most susceptible to the effects of a high-fat diet remain unknown. In addition, there are many unknown factors that can interact with a high-fat diet. Furthermore, the effects of high-fat diets can be inherited by offspring.

This Special Issue welcomes original research and review articles with clinical, experimental and epidemiological content concerning factors interacting with a high-fat diet and populations at risk for a high-fat diet.

Dr. Jiunn-Ming Sheen
